```

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

(Processes: process: TBP)+≡

    class(process_t), intent(inout) :: process
    class(expr_factory_t), intent(in) :: ef_weight
    allocate (process%config%ef_weight, source = ef_weight)
  end subroutine process_set_weight
```

MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI

object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

```

<Processes: process: TBP>+≡
  procedure :: compute_md5sum => process_compute_md5sum

<Processes: procedures>+≡
  subroutine process_compute_md5sum (process)
    class(process_t), intent(inout) :: process
    integer :: i
    call process%config%compute_md5sum ()
    do i = 1, process%config%n_components
      associate (component => process%component(i))
        if (component%active) then
          call component%compute_md5sum ()
        end if
      end associate
    end do
    call process%beam_config%compute_md5sum ()
    do i = 1, process%config%n_mci
      call process%mci_entry(i)%compute_md5sum &
        (process%config, process%component, process%beam_config)
    end do
  end subroutine process_compute_md5sum

```

Integration and event generation

The sampler test should just evaluate the squared matrix element `n_calls` times, discarding the results, and return. This can be done before integration, e.g., for timing estimates.

```

<Processes: process: TBP>+≡
  procedure :: sampler_test => process_sampler_test

<Processes: procedures>+≡
  subroutine process_sampler_test (process, instance, i_mci, n_calls)
    class(process_t), intent(inout) :: process
    type(process_instance_t), intent(inout), target :: instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: n_calls
    call process%mci_entry(i_mci)%sampler_test (instance, n_calls)
  end subroutine process_sampler_test

```

Integrate the process, using a previously initialized process instance. We select one of the available MCI integrators by its index `i_mci` and thus integrate over (structure functions and) phase space for the associated (group of) process component(s).

The finalizer should be called after all integration passes have been completed. It will, for instance, write a summary of the integration results.

`integrate_dummy` does a “dummy” integration in the sense that nothing is done but just empty integration results appended.

```

(Processes: process: TBP)+≡
  procedure :: integrate => process_integrate
  procedure :: final_integration => process_final_integration
  procedure :: integrate_dummy => process_integrate_dummy

  end function process_get_md5sum_cfg

```

28.4.2 Metadata

This information describes the process and its environment. It is fixed upon initialization.

The `id` string is the name of the process object, as given by the user. The matrix element generator will use this string for naming Fortran procedures and types, so it should qualify as a Fortran name.

The `num_id` is meaningful if nonzero. It is used for communication with external programs or file standards which do not support string IDs.

The `run_id` string distinguishes among several runs for the same process. It identifies process instances with respect to adapted integration grids and similar run-specific data. The run ID is kept when copying processes for creating instances, however, so it does not distinguish event samples.

The `var_list` is a snapshot of the variable list, taken at the point where the process was initialized.

The `lib` pointer accesses the process library where the process definition and the process driver are located.

The `lib_index` is the index of entry in the process library that corresponds to the current process.

The `component_id` array identifies the individual process components.

The `component_description` is an array of human-readable strings that characterize the process components, for instance `a, b => c, d`.

The `active` mask array marks those components which are active. The others are skipped.

28.4.3 Generic Configuration Data

This information concerns physical and technical properties of the process. It is fixed upon initialization, using data from the process specification and the variable list.

The number **n_in** is the number of incoming beam particles, simultaneously the number of incoming partons, 1 for a decay and 2 for a scattering process. (The number of outgoing partons may depend on the process component.)

The number **n_components** is the number of components that constitute the current process.

The number **n_terms** is the number of distinct contributions to the scattering matrix that constitute the current process. Each component may generate several terms.

The number **n_mci** is the number of independent MC integration configurations that this process uses. Distinct process components that share a MCI configuration may be combined pointwise. (Nevertheless, a given MC variable set may correspond to several “nearby” kinematical configurations.) This is also the number of distinct sampling-function results that this process can generate. Process components that use distinct variable sets are added only once after an integration pass has completed.

The **model** pointer identifies the physics model and its parameters. This is a pointer to an external object.

The **rng_factory** component spawns independent random-number generators for use in integration, event generation, and event postprocessing.

Various **parse_node_t** objects are taken from the SINDARIN input. They encode expressions for evaluating cuts and scales. The workspaces for evaluating those expressions are set up in the **effective_state** subobjects. Note that these are really pointers, so the actual nodes are not stored inside the process object.

The **md5sum** is taken and used to verify the process configuration when re-reading data from file.

```

Initialize. We use information from the process metadata and from the process library, given the process ID. We also store the currently active OS data set.

The model that we import here should be an instance of the global model. If we create the instance outside, we can make it an extension of the basic `model_data_t`. This will allow us to synchronize the variable list with the model. Using a pointer instead of an allocatable, we can guarantee the `target` attribute.

The RNG factory object is imported by moving the allocation.

```

<Processes: process config data: TBP>+≡
  procedure :: init => process_config_data_init

<Processes: procedures>+≡
  subroutine process_config_data_init &
    (config, meta, os_data, qcd, rng_factory, model)

      config%md5sum = md5sum (u)
      close (u)
    end if
  end subroutine process_config_data_compute_md5sum

```

28.4.4 Beam configuration

The object `data` holds all details about the initial beam configuration. The allocatable array `sf` holds the structure-function configuration blocks. There are `n_strfun` entries in the structure-function chain (not counting the initial beam object). We maintain `n_channel` independent parameterizations of this

chain. If this is greater than zero, we need a multi-channel sampling algorithm, where for each point one channel is selected to generate kinematics.

The number of parameters that are required for generating a structure-function chain is `n_sfpar`.

The flag `azimuthal_dependence` tells whether the process setup is symmetric about the beam axis in the c.m. system. This implies that there is no transversal beam polarization. The flag `lab_is_cm_frame` is obvious.

```

<Processes: process part types>+=
  type :: process_beam_config_t
    private
    type(beam_data_t) :: data
    integer :: n_strfun = 0
    integer :: n_channel = 1

      counter%passed = counter%passed + 1
    else
      counter%evaluated = counter%evaluated + 1
    end if
    counter%total = counter%total + 1
  end subroutine process_counter_record

```

28.4.5 Multi-channel integration

The `process_mci_entry_t` block contains, for each process component that is integrated independently, the configuration data for its MC input parameters. Each input parameter set is handled by a `mci_t` integrator.

The MC input parameter set is broken down into the parameters required by the structure-function chain and the parameters required by the phase space of the elementary process.

The MD5 sum collects all information about the associated processes that may affect the integration. It does not contain the MCI object itself or integration results.

MC integration is organized in passes. Each pass may consist of several iterations, and for each iteration there is a number of calls. We store explicitly the values that apply to the current pass. Previous values are archived in the `results` object.

The `counter` receives the counter statistics from the associated process instance, for diagnostics.

The `results` object records results, broken down in passes and iterations.

```

    end if
  end subroutine process_mci_entry_write_chain_weights

```

Initialize. From the existing configuration, we obtain the number of channels and the number of parameters, separately for the structure-function chain and for the associated process component. We assume that the phase-space object has already been configured.

The allocation of the MCI integrator with the appropriate concrete type is the duty of the process core.

We assume that there is only one component associated with a MCI entry. This restriction should be relaxed.

```

```

Test the MCI sampler by calling it a given number of time, discarding the results. The instance should be initialized.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

```

<Processes: process mci entry: TBP>+≡
    procedure :: sampler_test => process_mci_entry_sampler_test

<Processes: procedures>+≡
    subroutine process_mci_entry_sampler_test (mci_entry, instance, n_calls)
        class(process_mci_entry_t), intent(inout) :: mci_entry
        type(process_instance_t), intent(inout), target :: instance

```

```

integer, intent(in) :: n_calls
call instance%choose_mci (mci_entry%i_mci)
call instance%reset_counter ()
call mci_entry%mci%sampler_test (instance, n_calls)
mci_entry%counter = instance%get_counter ()
end subroutine process_mci_entry_sampler_test

```

Integrate. The instance should be initialized.

The `integrate` method counts as an integration pass; the pass count is increased by one. We transfer the pass parameters (number of iterations and number of calls) to the actual integration routine.

The `mci_entry` is `intent(inout)` because the integrator contains the random-number state.

Note: The results are written to screen and to logfile. This behavior is hardcoded.

  end subroutine process_mci_entry_prepare_simulation
```

Generate an event. The instance should be initialized, otherwise event generation is directed by the mci integrator subobject. The integrator instance is contained in a mci_work subobject of the process instance, which simultaneously serves as the sampler object. (We avoid the anti-aliasing rules if we assume that the sampling itself does not involve the integrator instance contained in the process instance.)

Regarding weighted events, we only take events which are valid, which means that they have valid kinematics and have passed cuts. Therefore, we have a rejection loop. For unweighted events, the unweighting routine should already take care of this.

```

28.4.6 Process Components

A process component is an individual contribution to a process (scattering or decay) which needs not be physical. The sum over all components should be physical.

The `index` identifies this component within its parent process.

The actual process component is stored in the `core` subobject. We use a polymorphic subobject instead of an extension of `process_component_t`, because the individual entries in the array of process components can have different types. In short, `process_component_t` is a wrapper for the actual process variants.

If the `active` flag is false, we should skip this component. This happens if the associated process has vanishing matrix element.

The index array `i_term` points to the individual terms generated by this component. The indices refer to the parent process.

The index `i_mci` is the index of the MC integrator and parameter set which are associated to this process component.

```

<Processes: process part types>+≡
    type :: process_component_t
    private
    type(process_component_def_t), pointer :: config => null ()
    integer :: index = 0
    class(prc_core_t), allocatable :: core
    class(prc_core_t), allocatable :: core_sub_born
    logical :: active = .false.
    class(mci_t), allocatable :: mci_template
    integer, dimension(:), allocatable :: i_term
    integer :: i_mci = 0
    class(phs_config_t), allocatable :: phs_config
    character(32) :: md5sum_phs = ""
    type(fks_template_t) :: fks_template
    contains
    <Processes: process component: TBP>
end type process_component_t

```

Finalizer. The MCI template may (potentially) need a finalizer. The process configuration finalizer may include closing an open scratch file.

```

28.4.7 Process terms

For straightforward tree-level calculations, each process component corresponds to a unique elementary interaction. However, in the case of NLO calculations with subtraction terms, a process component may split into several separate contributions to the scattering, which are qualified by interactions with distinct kinematics and particle content. We represent their configuration as `process_term_t` objects, the actual instances will be introduced below as `term_instance_t`. In any case, the process term contains an elementary interaction with a definite quantum-number and momentum content.

The index `i_term_global` identifies the term relative to the process.

The index `i_component` identifies the process component which generates this term, relative to the parent process.

The index `i_term` identifies the term relative to the process component (not the process).

The `data` subobject holds all process constants.

The number of allowed flavor/helicity/color combinations is stored as `n_allowed`. This is the total number of independent entries in the density matrix. For each combination, the index of the flavor, helicity, and color state is stored in the arrays `flv`, `hel`, and `col`, respectively.

The flag `rearrange` is true if we need to rearrange the particles of the hard interaction, to obtain the effective parton state.

The interaction `int` holds the quantum state for the (resolved) hard interaction, the parent-child relations of the particles, and their momenta. The momenta are not filled yet; this is postponed to copies of `int` which go into the process instances.

If recombination is in effect, we should allocate `int_eff` to describe the rearranged partonic state.

```

<Processes: process part types>+≡
  type :: process_term_t
    integer :: i_term_global = 0
    integer :: i_component = 0
    integer :: i_term = 0
    integer :: n_allowed = 0
    integer :: n_allowed_sub_born = 0
    type(process_constants_t) :: data
    real(default) :: alpha_s = 0

```

```

integer, dimension(:), allocatable :: flv, hel, col
logical :: rearrange = .false.
type(interaction_t) :: int
type(interaction_t), pointer :: int_eff => null ()
contains
  <Processes: process term: TBP>
end type process_term_t

```

For the output, we skip the process constants and the tables of allowed quantum numbers. Those can also be read off from the interaction object.

```

  <Processes: process term: TBP>≡
    procedure :: write => process_term_write

  <Processes: procedures>+≡
    subroutine process_term_write (term, unit)
      class(process_term_t), intent(in) :: term

        write (u, "(1x,A)") "Rearranged hard interaction:"
        call write_separator (u)
        call interaction_write (term%int_eff, u)
      end if
    end subroutine process_term_write

```

Write an account of all quantum number states and their current status.

```

  <Processes: process term: TBP>+≡
    procedure :: write_state_summary => process_term_write_state_summary

  <Processes: procedures>+≡
    subroutine process_term_write_state_summary (term, core, unit)
      class(process_term_t), intent(in) :: term
      class(prc_core_t), intent(in) :: core
      integer, intent(in), optional :: unit
      integer :: u, i, f, h, c
      type(state_iterator_t) :: it
      character :: sgn
      u = given_output_unit (unit)
      write (u, "(1x,A,I0)") "Term #", term%i_term_global
      call state_iterator_init (it, interaction_get_state_matrix_ptr (term%int))
      do while (state_iterator_is_valid (it))

```

```

        i = state_iterator_get_me_index (it)
        f = term%flv(i)
        h = term%hel(i)
        c = term%col(i)
        if (core%is_allowed (term%i_term, f, h, c)) then
            sgn = "+"
        else
            sgn = " "
        end if
        write (u, "(1x,A1,1x,I0,2x)", advance="no") sgn, i
        call quantum_numbers_write (state_iterator_get_quantum_numbers (it), u)
        write (u, *)
        call state_iterator_advance (it)
    end do
end subroutine process_term_write_state_summary

```

Finalizer: the `int` and potentially `int_eff` components have a finalizer that we must call.

```

<Processes: process term: TBP>+=
    procedure :: final => process_term_final

<Processes: procedures>+=
    subroutine process_term_final (term)
        class(process_term_t), intent(inout) :: term
        call interaction_final (term%int)
        if (term%rearrange) then
            call interaction_final (term%int_eff)
            deallocate (term%int_eff)
        end if
    end subroutine process_term_final

```

Initialize the term. We copy the process constants from the `core` object and set up the `int` hard interaction accordingly.

The `alpha_s` value is useful for writing external event records. This is the constant value which may be overridden by a event-specific running value. If the model does not contain the strong coupling, the value is zero.

The `rearrange` part is commented out; this or something equivalent could become relevant for NLO algorithms.

```

<Processes: process term: TBP>+=
    procedure :: init => process_term_init

<Processes: procedures>+=
    subroutine process_term_init &
        (term, i_term_global, i_component, i_term, core, model)
        class(process_term_t), intent(inout), target :: term
        integer, intent(in) :: i_term_global
        integer, intent(in) :: i_component
        integer, intent(in) :: i_term
        class(prc_core_t), intent(in) :: core
        class(model_data_t), intent(in), target :: model
        class(modelpar_data_t), pointer :: alpha_s_ptr
    !   type(var_list_t), pointer :: var_list
        term%i_term_global = i_term_global

```

```

term%i_component = i_component
term%i_term = i_term
call core%get_constants (term%data, i_term)
!   var_list => model%get_var_list_ptr ()
!   if (var_list_exists (var_list, var_str ("alphas"))) then
!       term%alpha_s = var_list_get_rval (var_list, var_str ("alphas"))
!   else
!       term%alpha_s = -1
!   end if
alpha_s_ptr => model%get_par_data_ptr (var_str ("alphas"))
if (associated (alpha_s_ptr)) then
    term%alpha_s = alpha_s_ptr%get_real ()
else
    term%alpha_s = -1
end if

call term%setup_interaction (core, model)
!   if (term%rearrange) then
!       call term%setup_effective_interaction (core, term%int, term%int_eff)
!   end if
end subroutine process_term_init

```

We fetch the process constants which determine the quantum numbers and use those to create the interaction. The interaction contains incoming and outgoing particles, no virtuals. The incoming particles are parents of the outgoing ones.

Keeping previous WHIZARD conventions, we invert the color assignment (but not flavor or helicity) for the incoming particles. When the color-flow square matrix is evaluated, this inversion is done again, so in the color-flow sequence we get the color assignments of the matrix element.

28.4.8 Default Iterations

If the user does not specify the passes and iterations for integration, we should be able to give reasonable defaults. These depend on the process, therefore we implement the following procedures as methods of the process object. The algorithm is not very sophisticated yet, it may be improved by looking at the process in more detail.

We investigate only the first process component, assuming that it characterizes the complexity of the process reasonable well.

The number of passes is limited to two: one for adaption, one for integration.

```

<Processes: process: TBP>+≡

```

```

procedure :: get_n_pass_default => process_get_n_pass_default

        end if
    end subroutine process_make_rng

```

28.4.10 Compute an amplitude

Each process variant should allow for computing an amplitude value directly, without generating a process instance.

The process component is selected by the index *i*. The term within the process component is selected by *j*. The momentum combination is transferred as the array *p*. The function sets the specific quantum state via the indices of a flavor *f*, helicity *h*, and color *c* combination. Each index refers to the list of flavor, helicity, and color states, respectively, as stored in the process data.

Optionally, we may set factorization and renormalization scale. If unset, the partonic c.m. energy is inserted.

The function checks arguments for validity. For invalid arguments (quantum states), we return zero.

```

(Processes: process: TBP)+≡
  procedure :: compute_amplitude => process_compute_amplitude

(Processes: procedures)+≡
  function process_compute_amplitude &

```

28.4.11 Process instances

Kinematics instance

In this data type we combine all objects (instances) necessary for generating (or recovering) a kinematical configuration. The components work together as an implementation of multi-channel phase space.

sf_chain is an instance of the structure-function chain. It is used both for generating kinematics and, after the proper scale has been determined, evaluating the structure function entries.

phs is an instance of the phase space for the elementary process.

The array **f** contains the products of the Jacobians that originate from parameter mappings in the structure-function chain or in the phase space. We allocate this explicitly if either **sf_chain** or **phs** are explicitly allocated, otherwise we can take over a pointer.

All components are implemented as pointers to (anonymous) targets. For each component, there is a flag that tells whether this component is to be regarded as a proper component ('owned' by the object) or as a pointer.

(Processes: types) +≡

```

type :: kinematics_t
  integer :: n_in = 0
  integer :: n_channel = 0
  integer :: selected_channel = 0
  type(sf_chain_instance_t), pointer :: sf_chain => null ()
  class(phs_t), pointer :: phs => null ()
  real(default), dimension(:), pointer :: f => null ()

```

```

end do
end subroutine kinematics_compute_other_channels

```

Just fetch the outgoing momenta of the `sf_chain` subobject, which become the incoming (seed) momenta of the hard interaction.

This is a stripped down-version of the above which we use when recovering kinematics. Momenta are known, but no MC parameters yet.

(We do not use the `get_out_momenta` method of the chain, since this relies on the structure-function interactions, which are not necessary filled here. We do rely on the momenta of the last evaluator in the chain, however.)

```

<Processes: kinematics: TBP>+≡
  procedure :: get_incoming_momenta => kinematics_get_incoming_momenta

<Processes: procedures>+≡
  subroutine kinematics_get_incoming_momenta (k, p)
    class(kinematics_t), intent(in) :: k

Process component instance

The actual calculation of a sampling point is done from here.

The `config` pointer accesses the corresponding configuration in the `process` object.

The `active` flag indicates that we are currently computing this component, together with all other components that share the same MC parameter set. Inactive components are using a different MC parameter set and are not in use for this sampling point.

The `k_seed` subobject contains the kinematics (structure-function chain, phase space, etc.) that implements the ‘seed’ configuration of momenta. This version of the process kinematics is accessed by the MCI setup.

`p_seed` is the array of momenta that we compute from the MC input parameters, via the `k_seed` subobject. Depending on the process variant, these may or may not coincide with the momenta that enter the process terms associated to this component.

The `tmp` object can be used for storing intermediate results. Its precise type and contents depend on the process variant.

```

end associate
end subroutine component_instance_compute_hard_kinematics

```

Here, we invert this. We fetch the incoming momenta which reside in the appropriate `sf_chain` object, stored within the `k_seed` subobject. On the other hand, we have the outgoing momenta of the effective interaction. We rely on the process core to compute the remaining seed momenta and to fill the momenta within the hard interaction. (The latter is trivial if hard and effective interaction coincide.)

After this is done, the incoming momenta in the trace evaluator that corresponds to the hard (effective) interaction, are still left undefined. We remedy this by calling `receive_kinematics` once.

Term instance

A `term_instance_t` object contains all data that describe a term. Each process component consists of one or more distinct terms which may differ in kinematics, but whose squared transition matrices have to be added pointwise.

The `active` flag is set when this term is connected to an active process component. Inactive terms are skipped for kinematics and evaluation.

The `k_term` object is the instance of the kinematics setup (structure-function chain, phase space, etc.) that applies specifically to this term. In ordinary cases, it consists of straight pointers to the seed kinematics.

The `amp` array stores the amplitude values when we get them from evaluating the associated matrix-element code.

The `int_hard` interaction describes the elementary hard process. It receives the momenta and the amplitude entries for each sampling point.

The `isolated` object holds the effective parton state for the elementary interaction. The amplitude entries are computed from `int_hard`.

The `connected` evaluator set convolutes this scattering matrix with the beam (and possibly structure-function) density matrix.

The `checked` flag is set once we have applied cuts on this term. The result of this is stored in the `passed` flag. Once the term has passed cuts, we calculate the various scale and weight expressions.

            call interaction_final (term%int_hard_real)
        end select
    end subroutine term_instance_final

```

For initialization, we make use of defined assignment for the `interaction_t` type. This creates a deep copy.

The hard interaction (incoming momenta) is linked to the structure function instance. In the isolated state, we either set pointers to both, or we create modified copies (`rearrange`) as effective structure-function chain and interaction,

respectively.

Finally, we set up the `subevt` component that will be used for evaluating observables, collecting particles from the trace evaluator in the effective connected state. Their quantum numbers must be determined by following back source links and set explicitly, since they are already eliminated in that trace.

The `rearrange` parts are still commented out; they could become relevant for a NLO algorithm.

Complete the kinematics computation for the effective parton states.

We assume that the `compute_hard_kinematics` method of the process component instance has already been called, so the `int_hard` contains the correct hard kinematics. The duty of this procedure is first to compute the effective kinematics and store this in the `int_eff` effective interaction inside the `isolated` parton state. The effective kinematics may differ from the kinematics in the hard interaction. It may involve parton recombination or parton splitting. The `rearrange_partons` method is responsible for this part.

We may also call a method to compute the effective structure-function chain at this point. This is not implemented yet.

In the simple case that no rearrangement is necessary, as indicated by the `rearrange` flag, the effective interaction is a pointer to the hard interaction, and we can skip the rearrangement method. Similarly for the effective structure-function chain. (If we have an algorithm that uses rearrangement, it should evaluate `k_term` explicitly.)

The final step of kinematics setup is to transfer the effective kinematics to the evaluators and to the `subevt`.

```

    case ('Real')
        call term%isolated_real%evaluate_trace ()
        call term%connected_real%evaluate_trace ()
    end select
end subroutine term_instance_evaluate_trace

```

Evaluate the extra data that we need for processing the object as a physical event.

```

<Processes: term instance: TBP>+≡
    procedure :: evaluate_event_data => term_instance_evaluate_event_data

<Processes: procedures>+≡
    subroutine term_instance_evaluate_event_data (term)
        class(term_instance_t), intent(inout) :: term
        select case (char (term%nlo_data%nlo_type))
        case ('Born', 'Virtual')
            call term%isolated%evaluate_event_data ()
            call term%connected%evaluate_event_data ()
        case ('Real')
            call term%isolated_real%evaluate_event_data ()
            call term%connected_real%evaluate_event_data ()
        end select
    end subroutine term_instance_evaluate_event_data

```

Return data that might be useful for external processing. The factorization scale:

```

<Processes: term instance: TBP>+≡
    procedure :: get_fac_scale => term_instance_get_fac_scale

<Processes: procedures>+≡
    function term_instance_get_fac_scale (term) result (fac_scale)
        class(term_instance_t), intent(in) :: term
        real(default) :: fac_scale
        fac_scale = term%fac_scale
    end function term_instance_get_fac_scale

```

We take the strong coupling from the process core. The value is calculated when a new event is requested, so we should call it only after the event has been evaluated. If it is not available there (a negative number is returned), we take the value stored in the term configuration, which should be determined by the model. If the model does not provide a value, the result is zero.

```

<Processes: term instance: TBP>+≡
    procedure :: get_alpha_s => term_instance_get_alpha_s

<Processes: procedures>+≡
    function term_instance_get_alpha_s (term, component) result (alpha_s)
        class(term_instance_t), intent(in) :: term
        type(component_instance_t), dimension(:), intent(in) :: component
        real(default) :: alpha_s
        integer :: i_component
        i_component = term%config%i_component

```

```

    associate (core => component(i_component)%config%core)
        alpha_s = core%get_alpha_s (component(i_component)%tmp)
    end associate
    if (alpha_s < 0) alpha_s = term%config%alpha_s
end function term_instance_get_alpha_s

```

MC parameter set and MCI instance

For each process component that is associated with a multi-channel integration (MCI) object, the `mci_work_t` object contains the currently active parameter set. It also holds the implementation of the `mci_instance_t` that the integrator needs for doing its work.

(Processes: types)+≡

```

type :: mci_work_t
    type(process_mci_entry_t), pointer :: config => null ()
    real(default), dimension(:), allocatable :: x
    class(mci_instance_t), pointer :: mci => null ()
    type(process_counter_t) :: counter
contains
    (Processes: mci work: TBP)
end type mci_work_t

```

First write configuration data, then the current values.

(Processes: mci work: TBP)≡

```

procedure :: write => mci_work_write

```

(Processes: procedures)+≡

```

subroutine mci_work_write (mci_work, unit, testflag)
    class(mci_work_t), intent(in) :: mci_work
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: testflag
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A,I0,A)") "Active MCI instance #", &
        mci_work%config%i_mci, " ="
    write (u, "(2x)", advance="no")
    do i = 1, mci_work%config%n_par
        write (u, "(1x,F7.5)", advance="no") mci_work%x(i)
        if (i == mci_work%config%n_par_sf) &
            write (u, "(1x,'|')", advance="no")
    end do
    write (u, *)
    if (associated (mci_work%mci)) then
        call mci_work%mci%write (u, pacify = testflag)
        call mci_work%counter%write (u)
    end if
end subroutine mci_work_write

```

The `mci` component may require finalization.

(Processes: mci work: TBP)+≡

```

procedure :: final => mci_work_final

```

```

<Processes: procedures>+≡
subroutine mci_work_final (mci_work)
  class(mci_work_t), intent(inout) :: mci_work
  if (associated (mci_work%mci)) then
    call mci_work%mci%final ()
    deallocate (mci_work%mci)
  end if
end subroutine mci_work_final

```

Initialize with the maximum length that we will need. Contents are not initialized.

The integrator inside the `mci_entry` object is responsible for allocating and initializing its own instance, which is referred to by a pointer in the `mci_work` object.

```

<Processes: mci work: TBP>+≡
  procedure :: init => mci_work_init

<Processes: procedures>+≡

    type(process_counter_t) :: counter
    counter = mci_work%counter
  end function mci_work_get_counter

```

The process instance

A process instance contains all process data that depend on the sampling point and thus change often. In essence, it is an event record at the elementary (parton) level. We do not call it such, to avoid confusion with the actual event records. If decays are involved, the latter are compositions of several elementary processes (i.e., their instances).

We implement the process instance as an extension of the `mci_sampler_t` that we need for computing integrals and generate events.

The base type contains: the `integrand`, the `selected_channel`, the two-dimensional array `x` of parameters, and the one-dimensional array `f` of Jacobians. These subobjects are public and used for communicating with the multi-channel integrator.

The `process` pointer accesses the process of which this record is an instance. It is required whenever the calculation needs invariant configuration data, therefore the process should stay in memory for the whole lifetime of its instances.

The `evaluation_status` code is used to check the current status. In particular, failure at various stages is recorded there.

The `count` object records process evaluations, broken down according to status.

The `sqme` value is the single real number that results from evaluating and tracing the kinematics and matrix elements. This is the number that is handed over to an integration routine.

The `weight` value is the event weight. It is defined when an event has been generated from the process instance, either weighted or unweighted. The value is the `sqme` value times Jacobian weights from the integration, or unity, respectively.

The `i_mci` index chooses a subset of components that are associated with a common parameter set and integrator, i.e., that are added coherently.

The `sf_chain` subobject is a realization of the beam and structure-function configuration in the `process` object. It is not used for calculation directly but serves as the template for the sf-chain instances that are contained in the `component` objects.

The `component` subobjects determine the state of each component.

The `term` subobjects are workspace for evaluating kinematics, matrix elements, cuts etc.

The `mci_work` subobject contains the array of real input parameters (random numbers) that generates the kinematical point. It also contains the workspace for the MC integrators. The active entry of the `mci_work` array is selected by the `i_mci` index above.

```

<Processes: public>+≡
    public :: process_instance_t

<Processes: types>+≡
    type, extends (mci_sampler_t) :: process_instance_t
        type(process_t), pointer :: process => null ()
        integer :: evaluation_status = STAT_UNDEFINED
        real(default) :: sqme = 0
        real(default), dimension(:), allocatable :: sqme_real

    end if
  end associate
end do
instance%evaluation_status = STAT_ACTIVATED
end subroutine process_instance_activate

```

Initialization connects the instance with a process. All initial information is transferred from the process object. The process object contains templates for the interaction subobjects (beam and term), but no evaluators. The initialization routine creates evaluators for the matrix element trace, other evaluators are left untouched.

The `instance` object must have the `target` attribute (also in any caller) since the initialization routine assigns various pointers to subobject of `instance`.

    if (config%sf_trace) then
      call instance%sf_chain%setup_tracing (config%sf_trace_file)
    end if
  end subroutine process_instance_setup_sf_chain

```

This initialization routine should be called only for process instances which we intend as a source for physical events. It initializes the evaluators in the parton states of the terms. They describe the (semi-)exclusive transition matrix and the distribution of color flow for the partonic process, convoluted with the beam and structure-function chain.

If the model is not provided explicitly, we may use the model instance that belongs to the process. However, an explicit model allows us to override particle settings.

```

(Processes: process instance: TBP)+≡
  procedure :: setup_event_data => process_instance_setup_event_data

(Processes: procedures)+≡
  subroutine process_instance_setup_event_data (instance, model)

    subroutine process_instance_set_mcpars (instance, x)
        class(process_instance_t), intent(inout) :: instance
        real(default), dimension(:), intent(in) :: x
        if (instance%evaluation_status == STAT_INITIAL) then
            associate (mci_work => instance%mci_work(instance%i_mci))
                call mci_work%set (x)
            end associate
            call instance%activate ()
        end if
    end subroutine

```

```
end subroutine process_instance_set_mcpair
```

Receive the beam momentum/momenta from a source interaction. This applies to a cascade decay process instance, where the ‘beam’ momentum varies event by event.

The master beam momentum array is contained in the main structure function chain subobject `sf_chain`. The sf-chain instance that reside in the components will take their beam momenta from there.

The procedure transforms the instance status into `STAT_BEAM_MOMENTA`. For process instance with fixed beam, this intermediate status is skipped.

```
(Processes: process instance: TBP)+≡
  procedure :: receive_beam_momenta => process_instance_receive_beam_momenta

(Processes: procedures)+≡
  subroutine process_instance_receive_beam_momenta (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%receive_beam_momenta ()
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_receive_beam_momenta
```

Set the beam momentum/momenta explicitly. Otherwise, analogous to the previous procedure.

```
(Processes: process instance: TBP)+≡
  procedure :: set_beam_momenta => process_instance_set_beam_momenta

(Processes: procedures)+≡
  subroutine process_instance_set_beam_momenta (instance, p)
    class(process_instance_t), intent(inout) :: instance
    type(vector4_t), dimension(:), intent(in) :: p
    if (instance%evaluation_status >= STAT_INITIAL) then
      call instance%sf_chain%set_beam_momenta (p)
      instance%evaluation_status = STAT_BEAM_MOMENTA
    end if
  end subroutine process_instance_set_beam_momenta
```

Recover the initial beam momenta (those in the `sf_chain` component), given a valid (recovered) `sf_chain_instance` in one of the active components. We need to do this only if the lab frame is not the c.m. frame, otherwise those beams would be fixed anyway.

```
(Processes: process instance: TBP)+≡
  procedure :: recover_beam_momenta => process_instance_recover_beam_momenta

(Processes: procedures)+≡
  subroutine process_instance_recover_beam_momenta (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    integer :: i
    if (.not. instance%process%beam_config%lab_is_cm_frame) then
      if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
        i = instance%term(i_term)%config%i_component
        call instance%component(i)%return_beam_momenta ()
      end if
    end if
  end subroutine process_instance_recover_beam_momenta
```

```

        end if
    end if
end subroutine process_instance_recover_beam_momenta

```

Explicitly choose MC integration channel. We assume here that the channel count is identical for all active components.

```

<Processes: process instance: TBP>+≡
    procedure :: select_channel => process_instance_select_channel

<Processes: procedures>+≡
    subroutine process_instance_select_channel (instance, channel)
        class(process_instance_t), intent(inout) :: instance
        integer, intent(in) :: channel
        instance%selected_channel = channel
    end subroutine process_instance_select_channel

```

First step of process evaluation: set up seed kinematics. That is, for each active process component, compute a momentum array from the MC input parameters.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Processes: process instance: TBP>+≡
    procedure :: compute_seed_kinematics => &
        process_instance_compute_seed_kinematics

<Processes: procedures>+≡
    subroutine process_instance_compute_seed_kinematics (instance, skip_term)

        logical :: real_phsp
        if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
            do i = 1, size (instance%component)
                if (instance%component(i)%active) then
                    select case (char (instance%component(i)%config%config%get_nlo_type()))
                    case ('Born', 'Virtual')
                        real_phsp = .false.
                    case ('Real')
                        real_phsp = .true.
                    end select
                    call instance%component(i)% &
                        compute_hard_kinematics (instance%term, skip_term, real_phsp)
                end if
            end do
            instance%evaluation_status = STAT_HARD_KINEMATICS
        end if
    end subroutine process_instance_compute_hard_kinematics

```

```

end if
end subroutine process_instance_compute_hard_kinematics

```

Inverse: recover seed kinematics. We know the beam momentum configuration and the outgoing momenta of the effective interaction, for one specific term.

```

⟨Processes: process instance: TBP⟩+=
  procedure :: recover_seed_kinematics => &
    process_instance_recover_seed_kinematics

⟨Processes: procedures⟩+=
  subroutine process_instance_recover_seed_kinematics (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
      associate (i_component => instance%term(i_term)%config%i_component)
        call instance%component(i_component)% &
          recover_seed_kinematics (instance%term(i_term))
      end associate
    end if
  end subroutine process_instance_recover_seed_kinematics

```

Third step of process evaluation: compute the effective momentum configurations, for all active terms, from the hard kinematics.

```

⟨Processes: process instance: TBP⟩+=
  procedure :: compute_eff_kinematics => &
    process_instance_compute_eff_kinematics

⟨Processes: procedures⟩+=
  subroutine process_instance_compute_eff_kinematics (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: i
    if (instance%evaluation_status >= STAT_HARD_KINEMATICS) then
      do i = 1, size (instance%term)
        if (present (skip_term)) then
          if (i == skip_term) cycle
        end if
        if (instance%term(i)%active) then
          call instance%term(i)% &
            compute_eff_kinematics (instance%component)
        end if
      end do
      instance%evaluation_status = STAT_EFF_KINEMATICS
    end if
  end subroutine process_instance_compute_eff_kinematics

```

Inverse: recover the hard kinematics from effective kinematics for one term, then compute effective kinematics for the other terms.

```

⟨Processes: process instance: TBP⟩+=
  procedure :: recover_hard_kinematics => &
    process_instance_recover_hard_kinematics

```

```

<Processes: procedures>+=
  subroutine process_instance_recover_hard_kinematics (instance, i_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_term
    integer :: i
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
      call instance%term(i_term)%recover_hard_kinematics (instance%component)
      do i = 1, size (instance%term)
        if (i /= i_term) then
          if (instance%term(i)%active) then
            call instance%term(i)% &
              compute_eff_kinematics (instance%component)
          end if
        end if
      end do
      instance%evaluation_status = STAT_EFF_KINEMATICS
    end if
  end subroutine process_instance_recover_hard_kinematics

```

Fourth step of process evaluation: check cuts for all terms. Where successful, compute any scales and weights. Otherwise, deactivate the term. If any of the terms has passed, set the state to STAT_PASSED_CUTS.

```

<Processes: process instance: TBP>+=
  procedure :: evaluate_expressions => &
    process_instance_evaluate_expressions

<Processes: procedures>+=
  subroutine process_instance_evaluate_expressions (instance)
    class(process_instance_t), intent(inout) :: instance
    integer :: i
    if (instance%evaluation_status >= STAT_EFF_KINEMATICS) then
      do i = 1, size (instance%term)
        if (instance%term(i)%active) then
          call instance%term(i)%evaluate_expressions ()
        end if
      end do
      if (any (instance%term%passed)) then
        instance%evaluation_status = STAT_PASSED_CUTS
      else
        instance%evaluation_status = STAT_FAILED_CUTS
      end if
    end if
  end subroutine process_instance_evaluate_expressions

```

Fifth step of process evaluation: fill the parameters for the non-selected ,channels, that have not been used for seeding. We should do this after evaluating cuts, since we may save some expensive calculations if the phase space point fails the cuts.

If `skip_term` is set, we skip the component that accesses this term. We can assume that the associated data have already been recovered, and we are just computing the rest.

```

<Processes: process instance: TBP>+=

```

```

procedure :: compute_other_channels => &
    process_instance_compute_other_channels

<Processes: procedures>+≡
subroutine process_instance_compute_other_channels (instance, skip_term)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in), optional :: skip_term
    integer :: channel, skip_component, i
    channel = instance%selected_channel
    if (channel == 0) then
        call msg_bug ("Compute other channels: undefined integration channel")
    end if
    if (present (skip_term)) then
        skip_component = instance%term(skip_term)%config%i_component
    else
        skip_component = 0
    end if
    if (instance%evaluation_status >= STAT_PASSED_CUTS) then
        do i = 1, size (instance%component)
            if (i == skip_component) cycle
            if (instance%component(i)%active) then
                call instance%component(i)%compute_other_channels &
                    (instance%mci_work(instance%i_mci), channel)
            end if
        end do
    end if
end subroutine process_instance_compute_other_channels

```

Sixth step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

```

<Processes: process instance: TBP>+≡
    procedure :: evaluate_trace => process_instance_evaluate_trace

<Processes: procedures>+≡
subroutine process_instance_evaluate_trace (instance)
    class(process_instance_t), intent(inout) :: instance
    integer :: i, j
    integer :: n_legs
    logical :: passed
    integer :: ireg
    instance%sqme = 0
    if (instance%evaluation_status >= STAT_PASSED_CUTS) then
        do i = 1, size (instance%term)
            associate (term => instance%term(i))
                if (term%active .and. term%passed) then
                    select case (char (term%nlo_data%nlo_type))
                    case ('Real')
                        instance%sqme_real = 0
                        n_legs = term%nlo_data%reg_data%nlegs_real
                        passed = .true.
                        ireg = 1
                        do j = 1, n_legs
                            if (any (term%nlo_data%reg_data%emitters == j)) then

```

```

        call term%nlo_data%set_active_emitter (j)
        call term%evaluate_interaction (instance%component)
        passed = passed .and. term%passed
        if (term%passed) then
            call term%evaluate_trace ()
            if (instance%component(i)%active) then
                call instance%component(i)%evaluate_sqme (instance%term)
                instance%sqme_real(ireg) = instance%component(i)%nlo_data%sqme_real
            end if
        end if
        ireg = ireg + 1
    end if
end do
if (passed) then
    instance%sqme = sum (instance%sqme_real)
    instance%evaluation_status = STAT_EVALUATED_TRACE
else
    instance%evaluation_status = STAT_FAILED_CUTS
end if
case ('Born', 'Virtual')
    call term%evaluate_interaction (instance%component)
    call term%evaluate_trace ()
end select
end if
end associate
end do
do i = 1, size (instance%component)
    associate (component => instance%component(i))
        if (component%active) then
            select case (char (component%config%config%get_nlo_type()))
            case ('Born', 'Virtual')
                call component%evaluate_sqme (instance%term)
                instance%sqme = instance%sqme + component%sqme
                instance%evaluation_status = STAT_EVALUATED_TRACE
            end select
        end if
    end associate
end do
else
    ! failed kinematics, failed cuts: set sqme to zero
    instance%sqme = 0
end if
end if
end subroutine process_instance_evaluate_trace

```

Final step of process evaluation: evaluate the matrix elements, and compute the trace (summed over quantum numbers) for all terms. Finally, sum up the terms, iterating over all active process components.

If **weight** is provided, we already know the kinematical event weight (the MCI weight which depends on the kinematics sampling algorithm, but not on the matrix element), so we do not need to take it from the MCI record.

(Processes: process instance: TBP)+≡

procedure :: evaluate_event_data => process_instance_evaluate_event_data

(Processes: procedures)+≡

```

subroutine process_instance_evaluate_event_data (instance, weight)
  class(process_instance_t), intent(inout) :: instance
  real(default), intent(in), optional :: weight
  integer :: i
  if (instance%evaluation_status >= STAT_EVALUATED_TRACE) then
    do i = 1, size (instance%term)
      associate (term => instance%term(i))
        if (term%active .and. term%passed) then
          call term%evaluate_event_data ()
        end if
      end associate
    end do
    if (present (weight)) then
      instance%weight = weight
    else
      instance%weight = &
        instance%mc_i_work(instance%i_mci)%mc_i%get_event_weight ()
      instance%excess = &
        instance%mc_i_work(instance%i_mci)%mc_i%get_event_excess ()
    end if
    instance%evaluation_status = STAT_EVENT_COMPLETE
  else
    ! failed kinematics etc.: set weight to zero
    instance%weight = 0
  end if
end subroutine process_instance_evaluate_event_data

```

For unweighted event generation, we should reset the reported event weight to unity (signed) or zero. The latter case is appropriate for an event which failed for whatever reason.

```

<Processes: process instance: TBP>+≡
  procedure :: normalize_weight => process_instance_normalize_weight

<Processes: procedures>+≡
  subroutine process_instance_normalize_weight (instance)
    class(process_instance_t), intent(inout) :: instance
    if (instance%weight /= 0) then
      instance%weight = sign (1._default, instance%weight)
    end if
  end subroutine process_instance_normalize_weight

```

This is a convenience routine that performs the computations of the steps 1 to 5 in a single step. The arguments are the input for `set_mcpair`. After this, the evaluation status should be either `STAT_FAILED_KINEMATICS`, `STAT_FAILED_CUTS` or `STAT_EVALUATED_TRACE`.

Before calling this, we should call `choose_mci`.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate_sqme => process_instance_evaluate_sqme

<Processes: procedures>+≡
  subroutine process_instance_evaluate_sqme (instance, channel, x)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel

```

```

real(default), dimension(:), intent(in) :: x
call instance%reset ()
call instance%set_mcpair (x)
call instance%select_channel (channel)
call instance%compute_seed_kinematics ()
call instance%compute_hard_kinematics ()
call instance%compute_eff_kinematics ()
call instance%evaluate_expressions ()
call instance%compute_other_channels ()
call instance%evaluate_trace ()
end subroutine process_instance_evaluate_sqme

```

This is the inverse. Assuming that the final trace evaluator contains a valid momentum configuration, recover kinematics and recalculate the matrix elements and their trace.

To be precise, we first recover kinematics for the given term and associated component, then recalculate from that all other terms and active components. The `channel` is not really required to obtain the matrix element, but it allows us to reconstruct the exact MC parameter set that corresponds to the given phase space point.

Before calling this, we should call `choose_mci`.

```

<Processes: process instance: TBP>+≡
  procedure :: recover => process_instance_recover

<Processes: procedures>+≡
  subroutine process_instance_recover (instance, channel, i_term, update_sqme)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: channel
    integer, intent(in) :: i_term
    logical, intent(in) :: update_sqme
    call instance%activate ()
    instance%evaluation_status = STAT_EFF_KINEMATICS
    call instance%recover_hard_kinematics (i_term)
    call instance%recover_seed_kinematics (i_term)
    call instance%select_channel (channel)
    call instance%recover_mcpair (i_term)
    call instance%recover_beam_momenta (i_term)
    call instance%compute_seed_kinematics (i_term)
    call instance%compute_hard_kinematics (i_term)
    call instance%compute_eff_kinematics (i_term)
    call instance%compute_other_channels (i_term)
    call instance%evaluate_expressions ()
    if (update_sqme) call instance%evaluate_trace ()
  end subroutine process_instance_recover

```

The `evaluate` method is required by the `sampler_t` base type of which the process instance is an extension.

The requirement is that after the process instance is evaluated, the integrand, the selected channel, the x array, and the f Jacobian array are exposed by the `sampler_t` object.

```

<Processes: process instance: TBP>+≡
  procedure :: evaluate => process_instance_evaluate

```

```

<Processes: procedures>+=
  subroutine process_instance_evaluate (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(out) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call sampler%evaluate_sqme (c, x_in)
    if (sampler%is_valid ()) call sampler%fetch (val, x, f)
    call sampler%record_call ()
  end subroutine process_instance_evaluate

```

The phase-space point is valid if the event has valid kinematics and has passed the cuts.

```

<Processes: process instance: TBP>+=
  procedure :: is_valid => process_instance_is_valid

<Processes: procedures>+=
  function process_instance_is_valid (sampler) result (valid)
    class(process_instance_t), intent(in) :: sampler
    logical :: valid
    valid = sampler%evaluation_status >= STAT_PASSED_CUTS
  end function process_instance_is_valid

```

The `rebuild` method should rebuild the kinematics section out of the `x_in` parameter set. The integrand value `val` should not be computed, but is provided as input.

```

<Processes: process instance: TBP>+=
  procedure :: rebuild => process_instance_rebuild

<Processes: procedures>+=
  subroutine process_instance_rebuild (sampler, c, x_in, val, x, f)
    class(process_instance_t), intent(inout) :: sampler
    integer, intent(in) :: c
    real(default), dimension(:), intent(in) :: x_in
    real(default), intent(in) :: val
    real(default), dimension(:,:), intent(out) :: x
    real(default), dimension(:), intent(out) :: f
    call msg_bug ("process_instance_rebuild not implemented yet")
    x = 0
    f = 0
  end subroutine process_instance_rebuild

```

This is another method required by the `sampler_t` base type: fetch the data that are relevant for the MCI record.

```

<Processes: process instance: TBP>+=
  procedure :: fetch => process_instance_fetch

<Processes: procedures>+=
  subroutine process_instance_fetch (sampler, val, x, f)
    class(process_instance_t), intent(in) :: sampler
    real(default), intent(out) :: val

```

```

real(default), dimension(:,:), intent(out) :: x
real(default), dimension(:), intent(out) :: f
integer :: i, cc
integer :: n_channel
val = 0
FIND_COMPONENT: do i = 1, size (sampler%component)
  associate (component => sampler%component(i))
    if (component%active) then
      associate (k => component%k_seed)
        n_channel = k%n_channel
        do cc = 1, n_channel
          call k%get_mcpair (cc, x(:,cc))
        end do
        f = k%f
        val = sampler%sqme * k%phs_factor
      end associate
    end if
  end associate
end do FIND_COMPONENT
end subroutine process_instance_fetch

```

Initialize and finalize event generation for the specified MCI entry.

```

<Processes: process instance: TBP>+≡
  procedure :: init_simulation => process_instance_init_simulation
  procedure :: final_simulation => process_instance_final_simulation

<Processes: procedures>+≡
  subroutine process_instance_init_simulation (instance, i_mci, safety_factor)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    real(default), intent(in), optional :: safety_factor
    call instance%mci_work(i_mci)%init_simulation (safety_factor)
  end subroutine process_instance_init_simulation

  subroutine process_instance_final_simulation (instance, i_mci)
    class(process_instance_t), intent(inout) :: instance
    integer, intent(in) :: i_mci
    call instance%mci_work(i_mci)%final_simulation ()
  end subroutine process_instance_final_simulation

```

28.4.12 Accessing the process instance

Once the seed kinematics is complete, we can retrieve the MC input parameters for all channels, not just the seed channel.

Note: We choose the first active component. This makes sense only if the seed kinematics is identical for all active components.

```

<Processes: process instance: TBP>+≡
  procedure :: get_mcpair => process_instance_get_mcpair

<Processes: procedures>+≡
  subroutine process_instance_get_mcpair (instance, channel, x)

```

```

class(process_instance_t), intent(inout) :: instance
integer, intent(in) :: channel
real(default), dimension(:), intent(out) :: x
integer :: i
if (instance%evaluation_status >= STAT_SEED_KINEMATICS) then
  do i = 1, size (instance%component)
    if (instance%component(i)%active) then
      call instance%component(i)%k_seed%get_mcpair (channel, x)
      return
    end if
  end do
  call msg_bug ("Process instance: get_mcpair: no active channels")
else
  call msg_bug ("Process instance: get_mcpair: no seed kinematics")
end if
end subroutine process_instance_get_mcpair

```

Return true if the `sque` value is known. This also implies that the event is kinematically valid and has passed all cuts.

```

<Processes: process instance: TBP>+≡
  procedure :: has_evaluated_trace => process_instance_has_evaluated_trace

<Processes: procedures>+≡
  function process_instance_has_evaluated_trace (instance) result (flag)
    class(process_instance_t), intent(in) :: instance
    logical :: flag
    flag = instance%evaluation_status >= STAT_EVALUATED_TRACE
  end function process_instance_has_evaluated_trace

```

Return true if the event is complete. In particular, the event must be kinematically valid, passed all cuts, and the event data have been computed.

```

<Processes: process instance: TBP>+≡
  procedure :: is_complete_event => process_instance_is_complete_event

<Processes: procedures>+≡
  function process_instance_is_complete_event (instance) result (flag)
    class(process_instance_t), intent(in) :: instance
    logical :: flag
    flag = instance%evaluation_status >= STAT_EVENT_COMPLETE
  end function process_instance_is_complete_event

```

Select a term for the process instance which is to provide the event record.

Note: this should be done using random numbers and applying probabilities for the various terms and components that belong to the selected MCI group. The current implementation simply selects the first term for the first active component.

```

<Processes: process instance: TBP>+≡
  procedure :: select_i_term => process_instance_select_i_term

<Processes: procedures>+≡
  subroutine process_instance_select_i_term (instance, i_term)
    class(process_instance_t), intent(in) :: instance
    integer, intent(out) :: i_term

```

```

integer :: i_mci, i_component
i_mci = instance%i_mci
i_component = instance%process%pci_entry(i_mci)%i_component(1)
i_term = instance%process%component(i_component)%i_term(1)
end subroutine process_instance_select_i_term

```

Return pointer to the master beam interaction.

```

```

28.4.13 Particle sets

Here we provide two procedures that convert the process instance from/to a particle set. The conversion applies to the trace evaluator which has no quantum-number information, thus it involves only the momenta and the parent-child relations. We keep virtual particles.

Nevertheless, it is possible to reconstruct the complete structure from a particle set. The reconstruction implies a re-evaluation of the structure function and matrix-element codes.

The `i_term` index is needed for both input and output, to select among different active trace evaluators.

In both cases, the `instance` object must be properly initialized.

```

<Processes: process instance: TBP>+≡
  procedure :: get_trace => process_instance_get_trace
  procedure :: set_trace => process_instance_set_trace

<Processes: procedures>+≡
  subroutine process_instance_get_trace (instance, pset, i_term)
    class(process_instance_t), intent(in), target :: instance

```

```

type(particle_set_t), intent(out) :: pset
integer, intent(in) :: i_term
type(interaction_t), pointer :: int
logical :: ok
int => instance%get_trace_int_ptr (i_term)
call particle_set_init (pset, ok, int, int, FM_IGNORE_HELICITY, &
    [0._default, 0._default], .false., .true.)
end subroutine process_instance_get_trace

subroutine process_instance_set_trace (instance, pset, i_term, recover_beams)

    procedure :: display_real_kinematics => process_instance_display_real_kinematics

<Processes: procedures>+≡
    subroutine process_instance_display_real_kinematics (instance, i)
    class(process_instance_t), intent(in) :: instance
    integer, intent(in) :: i
    if (instance%term(i)%nlo_data%counter_exists) &
        call instance%term(i)%nlo_data%counter%display ()
    end subroutine process_instance_display_real_kinematics

```

The `pacify` subroutine has the purpose of setting numbers to zero which are (by comparing with a `tolerance` parameter) considered equivalent with zero. We do this in some unit tests. Here, we apply this to the phase space subobject of the process instance.

```

<Processes: public>+≡
    public :: pacify

<Processes: interfaces>≡
    interface pacify
        module procedure pacify_process_instance
    end interface pacify

<Processes: procedures>+≡
    subroutine pacify_process_instance (instance)
    type(process_instance_t), intent(inout) :: instance
    integer :: i
    do i = 1, size (instance%component)
        call pacify (instance%component(i)%k_seed%phs)
    end do
    end subroutine pacify_process_instance

```

28.4.14 Unit tests

```
<Processes: public>+≡
  public :: processes_test

<Processes: tests>≡
  subroutine processes_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
<Processes: execute tests>
  end subroutine processes_test
```

Test process type

For the following tests, we define a simple implementation of the abstract `prc_core_t`, designed such as to complement the `prc_test_t` process definition type.

Note that it is not given that the actual process is defined as `prc_test_t` type. We enforce this by calling `prc_test_create_library`. The driver component in the process core will then become of type `prc_test_t`.

```
<Processes: public>+≡
  public :: test_t

<Processes: test types>≡
  type, extends (prc_core_t) :: test_t
  contains
    procedure :: write => test_write
    procedure :: needs_mcset => test_needs_mcset
    procedure :: get_n_terms => test_get_n_terms
    procedure :: is_allowed => test_is_allowed
    procedure :: compute_hard_kinematics => test_compute_hard_kinematics
    procedure :: compute_eff_kinematics => test_compute_eff_kinematics
    procedure :: recover_kinematics => test_recover_kinematics
    procedure :: compute_amplitude => test_compute_amplitude
  end type test_t

<Processes: tests>+≡
  subroutine test_write (object, unit)
    class(test_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    write (u, "(3x,A)") "test type implementing prc_test"
  end subroutine test_write
```

This process type always needs a MC parameter set and a single term. This only state is always allowed.

```
<Processes: tests>+≡
  function test_needs_mcset (object) result (flag)
    class(test_t), intent(in) :: object
    logical :: flag
    flag = .true.
```

```

end function test_needs_mcset

function test_get_n_terms (object) result (n)
  class(test_t), intent(in) :: object
  integer :: n
  n = 1
end function test_get_n_terms

function test_is_allowed (object, i_term, f, h, c) result (flag)
  class(test_t), intent(in) :: object
  integer, intent(in) :: i_term, f, h, c
  logical :: flag
  flag = .true.
end function test_is_allowed

```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

```

<Processes: tests>+≡
  subroutine test_compute_hard_kinematics &
    (object, p_seed, i_term, int_hard, tmp)
    class(test_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(in) :: p_seed
    integer, intent(in) :: i_term
    type(interaction_t), intent(inout) :: int_hard
    class(workspace_t), intent(inout), allocatable :: tmp
    call interaction_set_momenta (int_hard, p_seed)
  end subroutine test_compute_hard_kinematics

```

This procedure is not called for `test_t`, just a placeholder.

```

<Processes: tests>+≡
  subroutine test_compute_eff_kinematics &
    (object, i_term, int_hard, int_eff, tmp)
    class(test_t), intent(in) :: object
    integer, intent(in) :: i_term
    type(interaction_t), intent(in) :: int_hard
    type(interaction_t), intent(inout) :: int_eff
    class(workspace_t), intent(inout), allocatable :: tmp
  end subroutine test_compute_eff_kinematics

```

Transfer the incoming momenta of `p_seed` directly to the effective interaction, and vice versa for the outgoing momenta.

`int_hard` is left untouched since `int_eff` is an alias (via pointer) to it.

```

<Processes: tests>+≡
  subroutine test_recover_kinematics &
    (object, p_seed, int_hard, int_eff, tmp)
    class(test_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(inout) :: p_seed
    type(interaction_t), intent(inout) :: int_hard
    type(interaction_t), intent(inout) :: int_eff
    class(workspace_t), intent(inout), allocatable :: tmp
    integer :: n_in
    n_in = interaction_get_n_in (int_eff)

```

```

        call interaction_set_momenta (int_eff, p_seed(1:n_in), outgoing = .false.)
        p_seed(n_in+1:) = interaction_get_momenta (int_eff, outgoing = .true.)
    end subroutine test_recover_kinematics

```

Compute the amplitude. The driver ignores all quantum numbers and, in fact, returns a constant. Nevertheless, we properly transfer the momentum vectors.

```

<Processes: tests>+≡
    function test_compute_amplitude &
        (object, j, p, f, h, c, fac_scale, ren_scale, tmp) result (amp)
        class(test_t), intent(in) :: object
        integer, intent(in) :: j
        type(vector4_t), dimension(:), intent(in) :: p
        integer, intent(in) :: f, h, c
        real(default), intent(in) :: fac_scale, ren_scale
        class(workspace_t), intent(inout), allocatable, optional :: tmp
        complex(default) :: amp
        real(default), dimension(:,:), allocatable :: parray
        integer :: i, n_tot
        select type (driver => object%driver)
        type is (prc_test_t)
            if (driver%scattering) then
                n_tot = 4
            else
                n_tot = 3
            end if
            allocate (parray (0:3,n_tot))
            forall (i = 1:n_tot) parray(:,i) = vector4_get_components (p(i))
            amp = driver%get_amplitude (parray)
        end select
    end function test_compute_amplitude

```

Write an empty process object

The most trivial test is to write an uninitialized process object.

```

<Processes: execute tests>≡
    call test (processes_1, "processes_1", &
        "write an empty process object", &
        u, results)

<Processes: tests>+≡
    subroutine processes_1 (u)
        integer, intent(in) :: u
        type(process_t) :: process

        write (u, "(A)")  "* Test output: processes_1"
        write (u, "(A)")  "* Purpose: display an empty process object"
        write (u, "(A)")

        call process%write (.false., u)

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: processes_1"
    end subroutine processes_1

```

```
end subroutine processes_1
```

Initialize a process object

Initialize a process and display it.

```
<Processes: execute tests>+≡

Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

```

<Processes: execute tests>+≡
    call test (processes_8, "processes_8", &
        "process evaluation with structure functions", &
        u, results)

Colored interaction

This test specifically checks the transformation of process data (flavor, helicity, and color) into an interaction in a process term.

We use the `test_t` process core (which has no nontrivial particles), but call only the `is_allowed` method, which always returns true.

```

<Processes: execute tests>+≡
    call test (processes_13, "processes_13", &

call particle_set_final (pset)
call process_instance%final ()
deallocate (process_instance)

call process%final ()
deallocate (process)

write (u, "(A)")
write (u, "(A)")  "* Test output end: processes_17"

end subroutine processes_17

```

28.5 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

```

<process_stacks.f90>≡
  <File header>

  module process_stacks

    <Use strings>
    use io_units
    use format_utils, only: write_separator
    use unit_tests
    use diagnostics
    use os_interface
    use sm_qcd
    use variables
    use model_data
    use rng_base

    use process_libraries
    use prc_test
    use processes

    <Standard module head>

    <Process stacks: public>

    <Process stacks: types>

    contains

    <Process stacks: procedures>

    <Process stacks: tests>

  end module process_stacks

```

28.5.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

```

<Process stacks: public>≡
  public :: process_entry_t

<Process stacks: types>≡
  type, extends (process_t) :: process_entry_t
    type(process_entry_t), pointer :: next => null ()
  end type process_entry_t

```

28.5.2 The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

The process stack can be linked to another one. This allows us to work with stacks of local scope.

```
<Process stacks: public>+≡
    public :: process_stack_t

<Process stacks: types>+≡
    type :: process_stack_t
        integer :: n = 0
        type(process_entry_t), pointer :: first => null ()
        type(var_list_t), pointer :: var_list => null ()
        type(process_stack_t), pointer :: next => null ()
    contains
        <Process stacks: process stack: TBP>
    end type process_stack_t
```

Finalize partly: deallocate the process stack and variable list entries, but keep the variable list as an empty object. This way, the variable list links are kept.

```
<Process stacks: process stack: TBP>≡
    procedure :: clear => process_stack_clear

<Process stacks: procedures>≡
    subroutine process_stack_clear (stack)
        class(process_stack_t), intent(inout) :: stack
        type(process_entry_t), pointer :: process
        if (associated (stack%var_list)) then
            call var_list_final (stack%var_list)
        end if
        do while (associated (stack%first))
            process => stack%first
            stack%first => process%next
            call process%final ()
            deallocate (process)
        end do
        stack%n = 0
    end subroutine process_stack_clear
```

Finalizer. Clear and deallocate the variable list.

```
<Process stacks: process stack: TBP>+≡
    procedure :: final => process_stack_final

<Process stacks: procedures>+≡
    subroutine process_stack_final (object)
        class(process_stack_t), intent(inout) :: object
        type(process_entry_t), pointer :: process
        call object%clear ()
        if (associated (object%var_list)) then
            deallocate (object%var_list)
        end if
```

```
end subroutine process_stack_final
```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

```
<Process stacks: process stack: TBP>+≡
  procedure :: write => process_stack_write

<Process stacks: procedures>+≡
  recursive subroutine process_stack_write (object, unit, pacify)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: pacify
    type(process_entry_t), pointer :: process
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    select case (object%n)
    case (0)
      write (u, "(1x,A)") "Process stack: [empty]"
      call write_separator (u, 2)
    case default
      write (u, "(1x,A)") "Process stack:"
      process => object%first
      do while (associated (process))
        call process%write (.false., u, pacify = pacify)
        process => process%next
      end do
    end select
    if (associated (object%next)) then
      write (u, "(1x,A)") "[Processes from context environment:]"
      call object%next%write (u, pacify)
    end if
  end subroutine process_stack_write
```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

```
<Process stacks: process stack: TBP>+≡
  procedure :: write_var_list => process_stack_write_var_list

<Process stacks: procedures>+≡
  subroutine process_stack_write_var_list (object, unit)
    class(process_stack_t), intent(in) :: object
    integer, intent(in), optional :: unit
    if (associated (object%var_list)) then
      call var_list_write (object%var_list, unit)
    end if
  end subroutine process_stack_write_var_list
```

Short output.

```
<Process stacks: process stack: TBP>+≡
  procedure :: show => process_stack_show

<Process stacks: procedures>+≡
  recursive subroutine process_stack_show (object, unit)
```

```

class(process_stack_t), intent(in) :: object
integer, intent(in), optional :: unit
type(process_entry_t), pointer :: process
integer :: u
u = given_output_unit (unit)
select case (object%n)
case (0)
case default
    process => object%first
    do while (associated (process))
        call process%show (u, verbose=.false.)
        process => process%next
    end do
end select
if (associated (object%next)) call object%next%show ()
end subroutine process_stack_show

```

28.5.3 Link

Link the current process stack to a global one.

```

<Process stacks: process stack: TBP>+≡
    procedure :: link => process_stack_link

<Process stacks: procedures>+≡
    subroutine process_stack_link (local_stack, global_stack)
        class(process_stack_t), intent(inout) :: local_stack
        type(process_stack_t), intent(in), target :: global_stack
        local_stack%next => global_stack
    end subroutine process_stack_link

```

Initialize the process variable list and link the main variable list to it.

```

<Process stacks: process stack: TBP>+≡
    procedure :: init_var_list => process_stack_init_var_list

<Process stacks: procedures>+≡
    subroutine process_stack_init_var_list (stack, var_list)
        class(process_stack_t), intent(inout) :: stack
        type(var_list_t), intent(inout), optional :: var_list
        allocate (stack%var_list)
        if (present (var_list)) call var_list_link (var_list, stack%var_list)
    end subroutine process_stack_init_var_list

```

Link the process variable list to a global variable list.

```

<Process stacks: process stack: TBP>+≡
    procedure :: link_var_list => process_stack_link_var_list

<Process stacks: procedures>+≡
    subroutine process_stack_link_var_list (stack, var_list)
        class(process_stack_t), intent(inout) :: stack
        type(var_list_t), intent(in), target :: var_list
        call var_list_link (stack%var_list, var_list)
    end subroutine process_stack_link_var_list

```

28.5.4 Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is ‘owned’ by the stack and will be finalized when the stack is deleted.

```
<Process stacks: process stack: TBP>+≡
  procedure :: push => process_stack_push

<Process stacks: procedures>+≡
  subroutine process_stack_push (stack, process)
    class(process_stack_t), intent(inout) :: stack
    type(process_entry_t), intent(inout), pointer :: process
    process%next => stack%first
    stack%first => process
    process => null ()
    stack%n = stack%n + 1
  end subroutine process_stack_push
```

Initialize process variables for a given process ID, without setting values.

```
<Process stacks: process stack: TBP>+≡
  procedure :: init_result_vars => process_stack_init_result_vars

<Process stacks: procedures>+≡
  subroutine process_stack_init_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    call var_list_init_num_id (stack%var_list, id)
    call var_list_init_process_results (stack%var_list, id)
  end subroutine process_stack_init_result_vars
```

Fill process variables with values. This is executed after the integration pass.

Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

```
<Process stacks: process stack: TBP>+≡
  procedure :: fill_result_vars => process_stack_fill_result_vars

<Process stacks: procedures>+≡
  subroutine process_stack_fill_result_vars (stack, id)
    class(process_stack_t), intent(inout) :: stack
    type(string_t), intent(in) :: id
    type(process_t), pointer :: process
    process => stack%get_process_ptr (id)
    if (associated (process)) then
      call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
      if (process%has_integral ()) then
        call var_list_init_process_results (stack%var_list, id, &
          integral = process%get_integral (), &
          error = process%get_error ())
      end if
    else
      call msg_bug ("process_stack_fill_result_vars: unknown process ID")
    end if
  end subroutine process_stack_fill_result_vars
```

28.5.5 Data Access

Tell if a process exists.

```
<Process stacks: process stack: TBP>+≡
    procedure :: exists => process_stack_exists

<Process stacks: procedures>+≡
    function process_stack_exists (stack, id) result (flag)
        class(process_stack_t), intent(in) :: stack
        type(string_t), intent(in) :: id
        logical :: flag
        type(process_t), pointer :: process
        process => stack%get_process_ptr (id)
        flag = associated (process)
    end function process_stack_exists
```

Return a pointer to a process with specific ID. Look also at a linked stack, if necessary.

```
<Process stacks: process stack: TBP>+≡
    procedure :: get_process_ptr => process_stack_get_process_ptr

<Process stacks: procedures>+≡
    recursive function process_stack_get_process_ptr (stack, id) result (ptr)
        class(process_stack_t), intent(in) :: stack
        type(string_t), intent(in) :: id
        type(process_t), pointer :: ptr
        type(process_entry_t), pointer :: entry
        ptr => null ()
        entry => stack%first
        do while (associated (entry))
            if (entry%get_id () == id) then
                ptr => entry%process_t
                return
            end if
            entry => entry%next
        end do
        if (associated (stack%next)) ptr => stack%next%get_process_ptr (id)
    end function process_stack_get_process_ptr
```

28.5.6 Unit tests

```
<Process stacks: public>+≡
    public :: process_stacks_test

<Process stacks: tests>≡
    subroutine process_stacks_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Process stacks: execute tests>
    end subroutine process_stacks_test
```

Write an empty process stack

The most trivial test is to write an uninitialized process stack.

```
<Process stacks: execute tests>≡
    call test (process_stacks_1, "process_stacks_1", &
        "write an empty process stack", &
        u, results)

<Process stacks: tests>+≡
    subroutine process_stacks_1 (u)
        integer, intent(in) :: u
        type(process_stack_t) :: stack

        write (u, "(A)")  "* Test output: process_stacks_1"
        write (u, "(A)")  "* Purpose: display an empty process stack"
        write (u, "(A)")

        call stack%write (u)

        write (u, "(A)")
        write (u, "(A)")  "* Test output end: process_stacks_1"

    end subroutine process_stacks_1
```

Fill a process stack

Fill a process stack with two (identical) processes.

```
<Process stacks: execute tests>+≡
    call test (process_stacks_2, "process_stacks_2", &
        "fill a process stack", &
        u, results)

<Process stacks: tests>+≡
    subroutine process_stacks_2 (u)
        integer, intent(in) :: u
        type(process_stack_t) :: stack
        type(process_library_t), target :: lib
        type(string_t) :: libname
        type(string_t) :: procname
        type(string_t) :: run_id
        type(os_data_t) :: os_data
        type(qcd_t) :: qcd
        class(rng_factory_t), allocatable :: rng_factory
        class(model_data_t), pointer :: model
        type(process_entry_t), pointer :: process => null ()

        write (u, "(A)")  "* Test output: process_stacks_2"
        write (u, "(A)")  "* Purpose: fill a process stack"
        write (u, "(A)")

        write (u, "(A)")  "* Build, initialize and store two test processes"
        write (u, "(A)")

        libname = "process_stacks2"
```

```

procname = libname
call os_data_init (os_data)
allocate (rng_test_factory_t :: rng_factory)
call prc_test_create_library (libname, lib)

allocate (model)
call model%init_test ()

allocate (process)
run_id = "run1"
call process%init &
    (procname, run_id, lib, os_data, qcd, rng_factory, model)
call stack%push (process)

run_id = "run2"
call process%init &
    (procname, run_id, lib, os_data, qcd, rng_factory, model)
call stack%push (process)

call stack%write (u)

write (u, "(A)")
write (u, "(A)")  "* Cleanup"

call stack%final ()

write (u, "(A)")
write (u, "(A)")  "* Test output end: process_stacks_2"

end subroutine process_stacks_2

```

Fill a process stack

Fill a process stack with two (identical) processes.

```

<Process stacks: execute tests>+≡
    call test (process_stacks_3, "process_stacks_3", &
        "process variables", &
        u, results)

<Process stacks: tests>+≡
subroutine process_stacks_3 (u)
    integer, intent(in) :: u
    type(process_stack_t) :: stack
    type(model_data_t), target :: model
    type(string_t) :: procname
    type(process_entry_t), pointer :: process => null ()
    type(process_instance_t), target :: process_instance

    write (u, "(A)")  "* Test output: process_stacks_3"

```

```

write (u, "(A)")  "*" Purpose: setup process variables"
write (u, "(A)")

write (u, "(A)")  "*" Initialize process variables"
write (u, "(A)")

write (u, "(A)")  "* Test output end: process_stacks_4"

end subroutine process_stacks_4

```

Chapter 29

Parton shower and interface to hadronization

This is the code for the WHIZARD QCD parton shower for final state radiation (FSR) and initial state radiation (ISR) as well as the interface to the PYTHIA module for showering and hadronization.

29.1 Basics of the shower

```
<shower_base.f90>≡  
  <File header>  
  
  module shower_base  
  
    <Use kinds> !NODEP!  
    use constants !NODEP!  
    use tao_random_numbers !NODEP!  
  
    <Standard module head>  
  
    <Shower base: public>  
  
    <Shower base: parameters>  
  
    <Shower base: interfaces>  
  
    contains  
  
    <Shower base: procedures>  
  
  end module shower_base
```

29.1.1 PDF Parameters

The shower has to know about the PDF set used for the parent process, if any. We support the following:

```

<Shower base: parameters>+=
  integer, parameter, public :: STRF_NONE = 0
  integer, parameter, public :: STRF_LHAPDF6 = 1
  integer, parameter, public :: STRF_LHAPDF5 = 2
  integer, parameter, public :: STRF_PDF_BUILTIN = 3

```

29.1.2 Additional parameters

This decides whether to print out additional information.

```

<Shower base: parameters>+=
  logical, parameter, public :: D_print = .false.

```

These parameters are the cut-off scale t_{cut} , given in GeV^2 (PARJ(82)), the cut-off scale for the P_t^2 -ordered shower in GeV^2 , and the two shower parameters PARP(72) and PARP(61), respectively.

```

<Shower base: parameters>+=
  real(default), public :: D_Min_t = one
  real(default), public :: D_min_scale = 0.5_default
  real(default), public :: D_Lambda_fsr = 0.29_default
  real(default), public :: D_Lambda_isr = 0.29_default

```

The parameter MSTJ(45) gives the maximum number of flavours in gluon decay to quarks:

```

<Shower base: parameters>+=
  integer, public :: D_Nf = 5

```

These two parameters decide whether to use constant or running α_s in the form of the function $D.\alpha_s(t)$ for the FSR and ISR (MSTJ(44), MSTP(64)), respectively. The next is the parameter PARU(111), which sets the value for constant α_s , and the flag whether to use P_t -ordered ISR.

```

<Shower base: parameters>+=
  logical, public :: D_running_alpha_s_fsr = .true.
  logical, public :: D_running_alpha_s_isr = .true.
  real(default), public :: D_constalpha_s = 0.20_default
  logical, public :: isr_pt_ordered = .false.

```

This flag sets emitted timelike partons in the spacelike shower on shell, true corresponds to MSTP(63) = 0.

```

<Shower base: parameters>+=
  logical, public :: isr_only_onshell_emitted_partons = .true.

```

Flag whether ISR is angular ordered (MSTP(62)).

```

<Shower base: parameters>+=
  logical, public :: isr_angular_ordered = .true.

```

Treating either u and d , or all quarks except t as massless:

```

<Shower base: parameters>+=
  logical, public :: treat_light_quarks_massless = .true.
  logical, public :: treat_duscb_quarks_massless = .false.

```

The width and the cutoff of the Gaussian primordial k_t distribution, PARP(91) and PARP(93), in GeV:

```
<Shower base: parameters>+≡
  real(default), public :: primordial_kt_width = 1.5_default
  real(default), public :: primordial_kt_cutoff = five
```

The parameter PARP(66), the minimal energy of the emitted timelike parton in the ISR (PARP(65)), the factor for the first scale, as well as the factor by which the integral in the Sudakov factor is suppressed for the respective first scale in ISR. Higher values here correspond to higher starting scales.

```
<Shower base: parameters>+≡
  real(default), public :: maxz_isr = 0.999_default
  real(default), public :: minenergy_timelike = one
  real(default), public :: tscalefactor_isr = one
  real(default), public :: first_integral_suppression_factor = one
```

Temporary parameters for the P_t -ordered shower:

```
<Shower base: parameters>+≡
  real(default), public :: scalefactor1 = 0.02_default
  real(default), public :: scalefactor2 = 0.02_default
```

Then, there are the variables for the PDF functions:

```
<Shower base: parameters>+≡
  integer, public :: shower_pdf_set = 0
  integer, public :: shower_pdf_type = STRF_NONE
```

```
<Shower base: public>≡
  public :: D_alpha_s_isr
  public :: D_alpha_s_fsr
```

```
<Shower base: procedures>≡
  function D_alpha_s_isr (tin) result(alpha_s)
    real(default), intent(in) :: tin

Mass and mass squared selection functions. All masses are in GeV. Light quarks are assumed to be ordered, $m_1 < m_2 < m_3 \dots$, and they get current masses, not elementary ones. Mesons and baryons other than proton and neutron are needed as beam-remnants. Particles with PDG number zero are taken massless, as well as proper beam remnants and any other particles.

29.2.1 The basic type defintions

The type `parton_t` defines a parton for the shower. The `x` value of the parton is only needed for spacelike showers. The pointer `initial` is only needed for partons in initial showers, it points to the hadron the parton is coming from. An auxiliary value for the P_t -ordered ISR is `aux_pt`. Then, there are two auxiliary entries for the clustering of CKKW pseudo weights and CKKW matching, `ckkwlabel` and `ckkwscale`.

```

    procedure :: add_interaction_2ton => shower_add_interaction_2ton

<Shower core: procedures>≡
    subroutine shower_add_interaction_2ton (shower, partons)
        class(shower_t), intent(inout) :: shower
        type(parton_pointer_t), intent(in), dimension(:), allocatable :: partons
        type(ckkw_pseudo_shower_weights_t) :: ckkw_pseudo_weights
        call shower%add_interaction_2ton_CKKW (partons, ckkw_pseudo_weights)
    end subroutine shower_add_interaction_2ton

```

In this routine, `y` and `ymin` are the jet measures, `w` and `wmax` are weights, `s` is the kinematic energy squared of the interaction. The flag `isr_is_possible` checks whether the initial parton is set, lepton-hadron collisions are not implemented (yet). As a workaround: as WHIZARD can treat partons as massless, there might be partons with $E < m$: if such a parton is found, quarks will be treated massless.

C*****

C...UPVETO
C...Dummy routine, to be replaced by user, to veto event generation
C...on the parton level, after parton showers but before multiple
C...interactions, beam remnants and hadronization is added.
C...If resonances like W, Z, top, Higgs and SUSY particles are handed
C...undecayed from UPEVNT, or are generated by PYTHIA, they will also
C...be undecayed at this stage; if decayed their decay products will
C...have been allowed to shower.

C...All partons at the end of the shower phase are stored in the
C...HEPEVT commonblock. The interesting information is
C...NHEP = the number of such partons, in entries 1 <= i <= NHEP,
C...IDHEP(I) = the particle ID code according to PDG conventions,
C...PHEP(J,I) = the (p_x, p_y, p_z, E, m) of the particle.
C...All ISTHEP entries are 1, while the rest is zeroed.

C...The user decision is to be conveyed by the IVETO value.
C...IVETO = 0 : retain current event and generate in full;
C...      = 1 : abort generation of current event and move to next.

```

```

!C      KTYCUT gives the number of jets at each given YCUT value.
!C      KTYSUB gives the number of sub-jets at each given YCUT value.
!C      KTBEAM gives same info as KTCLUS but only for merges with the beam
!C      KTJOIN gives same info as KTCLUS but for merges of sub-jets.
!C      KTRECO reconstructs the jet momenta at a given value of YCUT.
!C      It also gives information on which jets at scale YCUT belong to
!C      which macro-jets at scale YMAC, for studying sub-jet properties.
!C      KTINCL reconstructs the jet momenta according to the inclusive jet
!C      definition of Ellis and Soper.
!C      KTISUB, KTIJOI and KTIREC are like KTYSUB, KTJOIN and KTRECO,
!C      except that they only apply to one inclusive jet at a time,
!C      with the pt of that jet automatically used for ECUT.
!C      KTWICH gives a list of which particles ended up in which jets.
!C      KTWCHS gives the same thing, but only for subjets.
!C      Note that the numbering of jets used by these two routines is
!C      guaranteed to be the same as that used by KTRECO.
!C
!C      The collision type and analysis type are indicated by the first
!C      argument of KTCLUS. IMODE=<TYPE><ANGLE><MONO><RECOM> where
!C      TYPE: 1=>ee, 2=>ep with p in -z direction, 3=>pe, 4=>pp
!C      ANGLE: 1=>angular kt def., 2=>DeltaR, 3=>f(DeltaEta,DeltaPhi)
!C              where f() $=2(\cosh(\eta)-\cos(\phi))$  is the QCD emission metric
!C      MONO: 1=>derive relative pseudoparticle angles from jets
!C              2=>monotonic definitions of relative angles
!C      RECOM: 1=>E recombination scheme, 2=>pt scheme, 3=>pt**2 scheme
!C
!C      There are also abbreviated forms for the most common combinations:
!C      IMODE=1 => E scheme in e+e-                (=1111)
!C              2 => E scheme in ep                  (=2111)
!C              3 => E scheme in pe                  (=3111)
!C              4 => E scheme in pp                  (=4111)
!C              5 => covariant E scheme in pp        (=4211)
!C              6 => covariant pt-scheme in pp       (=4212)
!C              7 => covariant monotonic pt**2-scheme in pp (=4223)
!C
!C      KTRECO no longer needs to reconstruct the momenta according to the
!C      same recombination scheme in which they were clustered. Its first
!C      argument gives the scheme, taking the same values as RECOM above.
!C
!C      Note that unlike previous versions, all variables which hold y
!C      values have been named in a consistent way:
!C      Y() is the output scale at which jets were merged,
!C      YCUT is the input scale at which jets should be counted, and
!C      jet-momenta reconstructed etc,
!C      YMAC is the input macro-jet scale, used in determining whether
!C      or not each jet is a sub-jet.
!C      The original scheme defined in our papers is equivalent to always
!C      setting YMAC=1.
!C      Whenever a YCUT or YMAC variable is used, it is rounded down
!C      infinitesimally, so that for example, setting YCUT=Y(2) refers
!C      to the scale where the event is 2-jet, even if rounding errors
!C      have shifted its value slightly.
!C
!C      An R parameter can be used in hadron-hadron collisions by

```

```

!C      calling KTCLUR instead of KTCLUS. This is as suggested by
!C      Ellis and Soper, but implemented slightly differently,
!C      as in M.H. Seymour, LU TP 94/2 (submitted to Nucl. Phys. B.).
!C      R**2 multiplies the single Kt everywhere it is used.
!C      Calling KTCLUR with R=1 is identical to calling KTCLUS.
!C      R plays a similar role to the jet radius in a cone-type algorithm,
!C      but is scaled up by about 40% (ie R=0.7 in a cone algorithm is
!C      similar to this algorithm with R=1).
!C      Note that R.EQ.1 must be used for the e+e- and ep versions,
!C      and is strongly recommended for the hadron-hadron version.
!C      However, R values smaller than 1 have been found to be useful for
!C      certain applications, particularly the mass reconstruction of
!C      highly-boosted colour-singlets such as high-pt hadronic Ws,
!C      as in M.H. Seymour, LU TP 93/8 (to appear in Z. Phys. C.).
!C      Situations in which R<1 is useful are likely to also be those in
!C      which the inclusive reconstruction method is more useful.
!C
!C      Also included is a set of routines for doing Lorentz boosts:
!C      KTLBST finds the boost matrix to/from the cm frame of a 4-vector
!C      KTRROT finds the rotation matrix from one vector to another
!C      KTMUL multiplies together two matrices
!C      KTMUL multiplies a vector by a matrix
!C      KTINVT inverts a transformation matrix (nb NOT a general 4 by 4)
!C      KTFRAM boosts a list of vectors between two arbitrary frames
!C      KTBREI boosts a list of vectors between the lab and Breit frames
!C      KTHADR boosts a list of vectors between the lab and hadronic cmf
!C      The last two need the momenta in the +z direction of the lepton
!C      and hadron beams, and the 4-momentum of the outgoing lepton.
!C
!C      The main reference is:
!C      S. Catani, Yu.L. Dokshitzer, M.H. Seymour and B.R. Webber,
!C      Nucl.Phys.B406(1993)187.
!C      The ep version was proposed in:
!C      S. Catani, Yu.L. Dokshitzer and B.R. Webber,
!C      Phys.Lett.285B(1992)291.
!C      The inclusive reconstruction method was proposed in:
!C      S.D. Ellis and D.E. Soper,
!C      Phys.Rev.D48(1993)3160.

CKKW (pseudo) weights

The type `ckkw_pseudo_shower_weights_t` gives the (relative) weights for different clusterings of the final particles, as given in Eq. (2.7) of hep-ph/0503281v1. Each particle has a binary labelling (power of 2) (first particle = 1, second particle = 2, third particle = 4, ...). Each recombination therefore corresponds to an integer, that is not a power of 2. For multiple subsequent recombinations, no different weights for different sequences of clustering are stored. It is assumed that the weight of a multiply recombined state is a combination of the states with one fewer recombination and that these states' contributions are proportional to their weights. For a $2-n$ event, the weights array thus has the size $2^{(2+n)-1}$. The `weights_by_type` array gives the weights depending on the type of the particle, the first index is the same as for weights, the second index gives the type of the new mother particle:

- 0: uncolored (γ , Z , W , Higgs)
- 1: colored (quark)
- 2: gluon
- 3: squark
- 4: gluino

`alphaS` gives the value for α_s used in the generation of the matrix element. This is needed for the reweighting using the values for a running α_s at the scales of the clusterings.

Chapter 30

Events

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

event_transforms Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

decays Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

showers Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

events Combine all pieces to generate full events.

30.1 Abstract Event Transforms

⟨Event transforms: procedures⟩

⟨Event transforms: tests⟩

end module event_transforms

```

30.1.1 Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified setting that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag that indicates this.

We will collect event transforms in a list, therefore we include `previous` and `next` pointers.

```

⟨Event transforms: public⟩≡
  public :: evt_t

⟨Event transforms: types⟩≡
  type, abstract :: evt_t
  type(process_t), pointer :: process => null ()
  type(process_instance_t), pointer :: process_instance => null ()
  class(model_data_t), pointer :: model => null ()

```

```

class(rng_t), allocatable :: rng
integer :: rejection_count = 0
logical :: particle_set_exists = .false.
type(particle_set_t) :: particle_set
class(evt_t), pointer :: previous => null ()
class(evt_t), pointer :: next => null ()
contains
  <Event transforms: evt: TBP>
end type evt_t

```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

```

<Event transforms: evt: TBP>≡
  procedure :: final => evt_final
  procedure :: base_final => evt_final

<Event transforms: procedures>≡
  subroutine evt_final (object)
    class(evt_t), intent(inout) :: object
    if (allocated (object%rng)) call object%rng%final ()
    if (object%particle_set_exists) &
      call particle_set_final (object%particle_set)
  end subroutine evt_final

```

Output. We can print r.n.g. info.

```

<Event transforms: evt: TBP>+≡
  procedure :: base_write => evt_write

<Event transforms: procedures>+≡
  subroutine evt_write (object, unit, verbose, testflag)
    class(evt_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose, testflag
    integer :: u
    u = given_output_unit (unit)
    if (associated (object%process)) then
      write (u, "(3x,A,A,A)") "Associated process: '", &
        char (object%process%get_id ()), "'"
    end if
    if (allocated (object%rng)) then
      call object%rng%write (u, 1)
      write (u, "(3x,A,I0)") "Number of tries = ", object%rejection_count
    end if
    if (object%particle_set_exists) then
      call write_separator (u)
      call particle_set_write (object%particle_set, u, testflag)
    end if
  end subroutine evt_write

```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

```

(Event transforms: evt: TBP)+≡
  procedure :: connect => evt_connect
  procedure :: base_connect => evt_connect

(Event transforms: procedures)+≡
  subroutine evt_connect (evt, process_instance, model, process_stack)
    class(evt_t), intent(inout), target :: evt
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    evt%process => process_instance%process
    evt%process_instance => process_instance
    evt%model => model
    call evt%process%make_rng (evt%rng)
  end subroutine evt_connect

```

Reset internal state.

```

(Event transforms: evt: TBP)+≡
  procedure :: reset => evt_reset
  procedure :: base_reset => evt_reset

(Event transforms: procedures)+≡
  subroutine evt_reset (evt)
    class(evt_t), intent(inout) :: evt
    evt%rejection_count = 0
    evt%particle_set_exists = .false.
  end subroutine evt_reset

```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_prepare_new_event), deferred :: prepare_new_event

(Event transforms: interfaces)≡
  interface
    subroutine evt_prepare_new_event (evt, i_mci, i_term)
      import
      class(evt_t), intent(inout) :: evt
      integer, intent(in) :: i_mci, i_term
    end subroutine evt_prepare_new_event
  end interface

```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_generate_weighted), deferred :: generate_weighted

(Event transforms: interfaces)+≡
  abstract interface
    subroutine evt_generate_weighted (evt, probability)

```

```

import
class(evt_t), intent(inout) :: evt
real(default), intent(out) :: probability
end subroutine evt_generate_weighted
end interface

```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

```

(Event transforms: evt: TBP)+≡
  procedure :: generate_unweighted => evt_generate_unweighted
  procedure :: base_generate_unweighted => evt_generate_unweighted
(Event transforms: procedures)+≡
  subroutine evt_generate_unweighted (evt)
    class(evt_t), intent(inout) :: evt
    real(default) :: p, x
    evt%rejection_count = 0
    REJECTION: do
      evt%rejection_count = evt%rejection_count + 1
      call evt%generate_weighted (p)
      if (signal_is_pending ()) return
      call evt%rng%generate (x)
      if (x < p) exit REJECTION
    end do REJECTION
  end subroutine evt_generate_unweighted

```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values `r`, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

```

(Event transforms: evt: TBP)+≡
  procedure (evt_make_particle_set), deferred :: make_particle_set
(Event transforms: interfaces)+≡
  interface
    subroutine evt_make_particle_set &
      (evt, factorization_mode, keep_correlations, r)
    import
    class(evt_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
  end subroutine evt_make_particle_set
  end interface

```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

```

(Event transforms: evt: TBP)+≡

```

```

    procedure :: set_particle_set => evt_set_particle_set
  <Event transforms: procedures>+≡
    subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
      class(evt_t), intent(inout) :: evt
      type(particle_set_t), intent(in) :: particle_set
      integer, intent(in) :: i_term, i_mci
      call evt%prepare_new_event (i_mci, i_term)
      evt%particle_set = particle_set
      evt%particle_set_exists = .true.
    end subroutine evt_set_particle_set

```

This procedure can help in the previous task, if the particles are available in the form of an interaction object. (We need two interactions, one with color summed over, and one with the probability distributed among flows.)

We use the two values from the random number generator for factorizing the state. For testing purposes, we can provide those numbers explicitly.

```

  <Event transforms: evt: TBP>+≡
    procedure :: factorize_interactions => evt_factorize_interactions
  <Event transforms: procedures>+≡
    subroutine evt_factorize_interactions &
      (evt, int_matrix, int_flows, factorization_mode, keep_correlations, r)
      class(evt_t), intent(inout) :: evt
      type(interaction_t), intent(in), target :: int_matrix, int_flows
      integer, intent(in) :: factorization_mode
      logical, intent(in) :: keep_correlations
      real(default), dimension(:), intent(in), optional :: r
      real(default), dimension(2) :: x
      if (present (r)) then
        if (size (r) == 2) then
          x = r
        else
          call msg_bug ("event factorization: size of r array must be 2")
        end if
      else
        call evt%rng%generate (x)
      end if
      call particle_set_init (evt%particle_set, evt%particle_set_exists, &
        int_matrix, int_flows, factorization_mode, x, &
        keep_correlations, keep_virtual=.true.)
      evt%particle_set_exists = .true.
    end subroutine evt_factorize_interactions

```

Mark the incoming particles as incoming in the particle set. This is necessary because in the interaction objects they are usually marked as virtual.

In the inquiry functions we set the term index to one; the indices of beams and incoming particles should be identical for all process terms.

We use the initial elementary process for obtaining the indices. Thus, we implicitly assume that the beam and incoming indices stay the same across event transforms. If this is not true for a transform (say, MPI), it should override this method.

```

  <Event transforms: evt: TBP>+≡

```

```

    procedure :: tag_incoming => evt_tag_incoming
  <Event transforms: procedures>+≡
    subroutine evt_tag_incoming (evt)
      class(evt_t), intent(inout) :: evt
      integer :: i_term, n_in
      integer, dimension(:), allocatable :: beam_index, in_index
      n_in = evt%process%get_n_in ()
      i_term = 1
      allocate (beam_index (n_in))
      call evt%process_instance%get_beam_index (i_term, beam_index)
      call particle_set_reset_status (evt%particle_set, &
        beam_index, PRT_BEAM)
      allocate (in_index (n_in))
      call evt%process_instance%get_in_index (i_term, in_index)
      call particle_set_reset_status (evt%particle_set, &
        in_index, PRT_INCOMING)
    end subroutine evt_tag_incoming

```

30.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The `generate` methods do nothing.

```

  <Event transforms: public>+≡
    public :: evt_trivial_t

  <Event transforms: types>+≡
    type, extends (evt_t) :: evt_trivial_t
      contains
      <Event transforms: evt trivial: TBP>
    end type evt_trivial_t

```

The finalizer is trivial. Some output:

```

  <Event transforms: evt trivial: TBP>≡
    procedure :: write => evt_trivial_write

  <Event transforms: procedures>+≡
    subroutine evt_trivial_write (object, unit, verbose, testflag)
      class(evt_trivial_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose, testflag
      integer :: u
      u = given_output_unit (unit)
      call write_separator (u, 2)
      write (u, "(1x,A)") "Event transform: trivial (hard process)"
      call write_separator (u)
      call object%base_write (u, testflag = testflag)
    end subroutine evt_trivial_write

```

Nothing to do here:

```

  <Event transforms: evt trivial: TBP>+≡
    procedure :: prepare_new_event => evt_trivial_prepare_new_event

```

```

<Event transforms: procedures>+≡
  subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: i_mci, i_term
    call evt%reset ()
  end subroutine evt_trivial_prepare_new_event

```

The weighted generator is, surprisingly, trivial.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: generate_weighted => evt_trivial_generate_weighted

<Event transforms: procedures>+≡
  subroutine evt_trivial_generate_weighted (evt, probability)
    class(evt_trivial_t), intent(inout) :: evt
    real(default), intent(out) :: probability
    probability = 1
  end subroutine evt_trivial_generate_weighted

```

This routine makes a particle set, using the associated process instance as-is.

```

<Event transforms: evt trivial: TBP>+≡
  procedure :: make_particle_set => evt_trivial_make_particle_set

<Event transforms: procedures>+≡
  subroutine evt_trivial_make_particle_set &
    (evt, factorization_mode, keep_correlations, r)
    class(evt_trivial_t), intent(inout) :: evt
    integer, intent(in) :: factorization_mode
    logical, intent(in) :: keep_correlations
    real(default), dimension(:), intent(in), optional :: r
    integer :: i_term
    type(interaction_t), pointer :: int_matrix, int_flows
    if (evt%process_instance%is_complete_event ()) then
      call evt%process_instance%select_i_term (i_term)
      int_matrix => evt%process_instance%get_matrix_int_ptr (i_term)
      int_flows => evt%process_instance%get_flows_int_ptr (i_term)
      call evt%factorize_interactions (int_matrix, int_flows, &
        factorization_mode, keep_correlations, r)
      call evt%tag_incoming ()
    else
      call msg_bug ("Event factorization: event is incomplete")
    end if
  end subroutine evt_trivial_make_particle_set

```

30.1.3 Unit tests

```

<Event transforms: public>+≡
  public :: event_transforms_test

<Event transforms: tests>≡
  subroutine event_transforms_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results

    <Decays: interfaces>

contains

    <Decays: procedures>

    <Decays: tests>

end module decays

```

30.2.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

```

<Decays: types>≡
    type, abstract :: any_config_t
    contains
    <Decays: any config: TBP>
end type any_config_t

```

Finalizer, depends on the implementation.

```

<Decays: any config: TBP>≡
    procedure (any_config_final), deferred :: final

<Decays: interfaces>≡
    interface
        subroutine any_config_final (object)
            import
            class(any_config_t), intent(inout) :: object
        end subroutine any_config_final
    end interface

```

The output is also deferred:

```

<Decays: any config: TBP>+≡
    procedure (any_config_write), deferred :: write

```

```

<Decays: interfaces>+≡
  interface
    subroutine any_config_write (object, unit, indent, verbose)
      import
      class(any_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
    end subroutine any_config_write
  end interface

```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
  type :: particle_config_t
    class(any_config_t), allocatable :: c
  end type particle_config_t

```

30.2.2 Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above. This also works around a compiler bug in gfortran.

```

<Decays: types>+≡
  type, abstract :: any_t
    contains
    <Decays: any: TBP>
  end type any_t

```

Finalizer, depends on the implementation.

```

<Decays: any: TBP>≡
  procedure (any_final), deferred :: final

<Decays: interfaces>+≡
  interface
    subroutine any_final (object)
      import
      class(any_t), intent(inout) :: object
    end subroutine any_final
  end interface

```

The output is also deferred:

```

<Decays: any: TBP>+≡
  procedure (any_write), deferred :: write

<Decays: interfaces>+≡
  interface
    subroutine any_write (object, unit, indent)
      import
      class(any_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent

```

```

        end subroutine any_write
    end interface

```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

```

<Decays: types>+≡
    type :: particle_out_t
        class(any_t), allocatable :: c
    end type particle_out_t

```

30.2.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

```

<Decays: types>+≡
    type :: decay_term_config_t
        type(particle_config_t), dimension(:), allocatable :: prt
        contains
        <Decays: decay term config: TBP>
    end type decay_term_config_t

```

Finalizer, recursive.

```

<Decays: decay term config: TBP>≡
    procedure :: final => decay_term_config_final

<Decays: procedures>≡
    recursive subroutine decay_term_config_final (object)
        class(decay_term_config_t), intent(inout) :: object
        integer :: i
        if (allocated (object%prt)) then
            do i = 1, size (object%prt)
                if (allocated (object%prt(i)%c)) call object%prt(i)%c%final ()
            end do
        end if
    end subroutine decay_term_config_final

```

Output, with optional indentation

```

<Decays: decay term config: TBP>+≡
    procedure :: write => decay_term_config_write

<Decays: procedures>+≡
    recursive subroutine decay_term_config_write (object, unit, indent, verbose)
        class(decay_term_config_t), intent(in) :: object
        integer, intent(in), optional :: unit, indent
        logical, intent(in), optional :: verbose
        integer :: i, j, u, ind
        logical :: verb
        u = given_output_unit (unit)
        ind = 0; if (present (indent)) ind = indent
        verb = .true.; if (present (verbose)) verb = verbose

```

```

call write_indent (u, ind)
write (u, "(1x,A)", advance="no") "Final state:"
do i = 1, size (object%prt)
  select type (prt_config => object%prt(i)%c)
  type is (stable_config_t)
    write (u, "(1x,A)", advance="no") &
      char (flavor_get_name (prt_config%flv(1)))
    do j = 2, size (prt_config%flv)
      write (u, "(:',A)", advance="no") &
        char (flavor_get_name (prt_config%flv(j)))
    end do
  type is (unstable_config_t)
    write (u, "(1x,A)", advance="no") &
      char (flavor_get_name (prt_config%flv))
  end select
end do
write (u, *)
if (verb) then
  do i = 1, size (object%prt)
    call object%prt(i)%c%write (u, ind)
  end do
end if
end subroutine decay_term_config_write

```

Initialize, given a set of flavors. For each flavor, we must indicate whether the particle is stable. The second index of the flavor array runs over alternatives for each decay product; alternatives are allowed only if the decay product is itself stable.

(Decays: decay term config: TBP)+≡

```

procedure :: init => decay_term_config_init

```

(Decays: procedures)+≡

```

recursive subroutine decay_term_config_init &

      end do
    end subroutine decay_term_generate

```

30.2.5 Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

```

<Decays: types>+≡
  type :: decay_root_config_t
    type(string_t) :: process_id
    type(process_t), pointer :: process => null ()
    class(model_data_t), pointer :: model => null ()
    type(decay_term_config_t), dimension(:), allocatable :: term_config
  contains
    <Decays: decay root config: TBP>
  end type decay_root_config_t

```

The finalizer is recursive since there may be cascade decays.

```

<Decays: decay root config: TBP>≡
  procedure :: final => decay_root_config_final

```

```

<Decays: procedures>+≡
recursive subroutine decay_root_config_final (object)
  class(decay_root_config_t), intent(inout) :: object
  integer :: i
  if (allocated (object%term_config)) then
    do i = 1, size (object%term_config)
      call object%term_config(i)%final ()
    end do
  end if
end subroutine decay_root_config_final

```

The output routine is also recursive, and it contains an adjustable indentation.

```

<Decays: decay root config: TBP>+≡
  procedure :: write => decay_root_config_write
  procedure :: write_header => decay_root_config_write_header

  end if
end subroutine decay_root_config_init

```

Declare a decay term, given an array of flavors.

<Decays: decay root config: TBP>+≡

```

procedure :: init_term => decay_root_config_init_term

```

<Decays: procedures>+≡

```

recursive subroutine decay_root_config_init_term &
  (decay, i, flv, stable, model, process_stack)
  class(decay_root_config_t), intent(inout) :: decay
  integer, intent(in) :: i
  type(flavor_t), dimension(:,:), intent(in) :: flv
  logical, dimension(:), intent(in) :: stable
  class(model_data_t), intent(in), target :: model
  type(process_stack_t), intent(in), optional :: process_stack
  call decay%term_config(i)%init (flv, stable, model, process_stack)
end subroutine decay_root_config_init_term

```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing

particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

```

<Decays: decay root config: TBP>+≡
  procedure :: connect => decay_root_config_connect

<Decays: procedures>+≡
  recursive subroutine decay_root_config_connect &
    (decay, process, model, process_stack, process_instance)
    class(decay_root_config_t), intent(out) :: decay
    type(process_t), intent(in), target :: process
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(process_instance_t), intent(in), optional, target :: process_instance
    type(connected_state_t), pointer :: connected_state
    type(interaction_t), pointer :: int
    type(flavor_t), dimension(:, :), allocatable :: flv
    logical, dimension(:), allocatable :: stable
    integer :: i
    call decay%init (model, process%get_id (), process%get_n_terms ())
    do i = 1, size (decay%term_config)
      if (present (process_instance)) then
        connected_state => process_instance%get_connected_state_ptr (i)
        int => connected_state%get_matrix_int_ptr ()
        call interaction_get_flv_out (int, flv)
      else
        call process%get_term_flv_out (i, flv)
      end if
      call flavor_set_model (flv, model)
      allocate (stable (size (flv, 1)))
      stable = flavor_is_stable (flv(:, 1))
      call decay%init_term (i, flv, stable, model, process_stack)
      deallocate (flv, stable)
    end do
    decay%process => process
  end subroutine decay_root_config_connect

```

Recursively compute widths, errors, and branching ratios.

```

<Decays: decay root config: TBP>+≡
  procedure :: compute => decay_root_config_compute

<Decays: procedures>+≡
  recursive subroutine decay_root_config_compute (decay)
    class(decay_root_config_t), intent(inout) :: decay
    integer :: i
    do i = 1, size (decay%term_config)
      call decay%term_config(i)%compute ()
    end do
  end subroutine decay_root_config_compute

```

30.2.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

```

<Decays: types>+≡
  type, abstract :: decay_gen_t
    type(decay_term_t), dimension(:), allocatable :: term
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
  contains
    <Decays: decay gen: TBP>
  end type decay_gen_t

```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

```

<Decays: types>+≡
  type, extends (decay_gen_t) :: decay_root_t
    type(decay_root_config_t), pointer :: config => null ()
  contains
    <Decays: decay root: TBP>
  end type decay_root_t

```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

```

<Decays: decay gen: TBP>≡
  procedure :: base_final => decay_gen_final

<Decays: procedures>+≡
  recursive subroutine decay_gen_final (object)
    class(decay_gen_t), intent(inout) :: object
    integer :: i
    if (allocated (object%term)) then
      do i = 1, size (object%term)
        call object%term(i)%final ()
      end do
    end if
  end subroutine decay_gen_final

```

No extra finalization for the decay root.

```

<Decays: decay root: TBP>≡
  procedure :: final => decay_root_final

<Decays: procedures>+≡
  subroutine decay_root_final (object)
    class(decay_root_t), intent(inout) :: object
    call object%base_final ()
  end subroutine decay_root_final

```

Output.

```

<Decays: decay root: TBP>+≡
  procedure :: write => decay_root_write

<Decays: procedures>+≡
  subroutine decay_root_write (object, unit)
    class(decay_root_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    if (associated (object%config)) then
      call object%config%write (unit, verbose = .false.)
    else
      write (u, "(1x,A)") "Final-state decay tree: [not configured]"
    end if
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI      = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI      = [undefined]"
    end if
    if (object%selected_term > 0) then
      write (u, "(3x,A,I0)") "Selected term    = ", object%selected_term
      call object%term(object%selected_term)%write (u, 1)
    else
      write (u, "(3x,A)") "Selected term    = [undefined]"
    end if
  end subroutine decay_root_write

```

Write the process instances, recursively.

```

<Decays: decay gen: TBP>+≡
  procedure :: write_process_instances => decay_gen_write_process_instances

<Decays: procedures>+≡
  recursive subroutine decay_gen_write_process_instances (decay, unit, verbose)
    class(decay_gen_t), intent(in) :: decay
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: verbose
    logical :: verb
    verb = .true.; if (present (verbose)) verb = verbose
    if (associated (decay%process_instance)) then
      if (verb) then
        call decay%process_instance%write (unit)
      else
        call decay%process_instance%write_header (unit)
      end if
    end if
    if (decay%selected_term > 0) then
      call decay%term(decay%selected_term)%write_process_instances (unit, verb)
    end if
  end subroutine decay_gen_write_process_instances

```

Generic initializer. All can be done recursively.

```

<Decays: decay gen: TBP>+≡
  procedure :: base_init => decay_gen_init

```

```

<Decays: procedures>+≡
recursive subroutine decay_gen_init (decay, term_config)
  class(decay_gen_t), intent(out) :: decay
  type(decay_term_config_t), dimension(:), intent(in), target :: term_config
  integer :: i
  allocate (decay%term (size (term_config)))
  do i = 1, size (decay%term)
    call decay%term(i)%init (term_config(i))
  end do
end subroutine decay_gen_init

```

Specific initializer. We assign the configuration object, which should correspond to a completely initialized decay configuration tree. We also connect to an existing process instance. Then, we recursively link the child interactions to the parent process.

```

<Decays: decay root: TBP>+≡
  procedure :: init => decay_root_init

<Decays: procedures>+≡
subroutine decay_root_init (decay_root, config, process_instance)
  class(decay_root_t), intent(out) :: decay_root
  type(decay_root_config_t), intent(in), target :: config
  type(process_instance_t), intent(in), target :: process_instance
  call decay_root%base_init (config%term_config)
  decay_root%config => config
  decay_root%process_instance => process_instance
  call decay_root%make_term_rng (config%process)
  call decay_root%link_term_interactions ()
end subroutine decay_root_init

```

Implement random-number generators for unstable decay selection in all terms. This is not recursive.

We also make use of the fact that `process` is a pointer; the (state of the RNG factory inside the) target process will be modified by the rng-spawning method, but not the pointer.

```

<Decays: decay gen: TBP>+≡
  procedure :: make_term_rng => decay_gen_make_term_rng

<Decays: procedures>+≡
subroutine decay_gen_make_term_rng (decay, process)
  class(decay_gen_t), intent(inout) :: decay
  type(process_t), intent(in), pointer :: process
  integer :: i
  do i = 1, size (decay%term)
    call decay%term(i)%make_rng (process)
  end do
end subroutine decay_gen_make_term_rng

```

Recursively link interactions of the enclosed decay terms to the corresponding terms in the current process instance.

Note: A bug in nagfor requires the extra `i_term` variable.

```

<Decays: decay gen: TBP>+≡
  procedure :: link_term_interactions => decay_gen_link_term_interactions

```

```

<Decays: procedures>+≡
recursive subroutine decay_gen_link_term_interactions (decay)
  class(decay_gen_t), intent(inout) :: decay
  integer :: i, i_term
  type(interaction_t), pointer :: trace
  associate (instance => decay%process_instance)
    do i = 1, size (decay%term)
      i_term = i
      trace => instance%get_trace_int_ptr (i_term)
      call decay%term(i_term)%link_interactions (trace)
    end do
  end associate
end subroutine decay_gen_link_term_interactions

```

Select a decay chain: decay modes and process components.

```

<Decays: decay root: TBP>+≡
  procedure :: select_chain => decay_root_select_chain

<Decays: procedures>+≡
subroutine decay_root_select_chain (decay_root)
  class(decay_root_t), intent(inout) :: decay_root
  if (decay_root%selected_term > 0) then
    call decay_root%term(decay_root%selected_term)%select_chain ()
  else
    call msg_bug ("Decays: no term selected for parent process")
  end if
end subroutine decay_root_select_chain

```

Generate a decay tree, i.e., for the selected term in the parent process, recursively generate a decay event for all unstable particles.

Factor out the trace of the connected state of the parent process. This trace should not be taken into account for unweighting the decay chain, since it was already used for unweighting the parent event, or it determines the overall event weight.

```

<Decays: decay root: TBP>+≡
  procedure :: generate => decay_root_generate

<Decays: procedures>+≡
subroutine decay_root_generate (decay_root)
  class(decay_root_t), intent(inout) :: decay_root
  type(connected_state_t), pointer :: connected_state
  if (decay_root%selected_term > 0) then
    connected_state => decay_root%process_instance%get_connected_state_ptr &
      (decay_root%selected_term)
    call connected_state%normalize_matrix_by_trace ()
    call decay_root%term(decay_root%selected_term)%generate ()
  else
    call msg_bug ("Decays: no term selected for parent process")
  end if
end subroutine decay_root_generate

```

30.2.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

```

<Decays: types>+≡
  type, extends (decay_root_config_t) :: decay_config_t
    real(default) :: weight = 0
    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: mci_selector
  contains
    <Decays: decay_config: TBP>
  end type decay_config_t

```

The output routine extends the decay-root writer by listing numerical component values.

```

<Decays: decay_config: TBP>≡
  procedure :: write => decay_config_write

<Decays: procedures>+≡
  recursive subroutine decay_config_write (object, unit, indent, verbose)
    class(decay_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,A)") "Decay:"
    call object%write_header (unit, indent)
    call write_indent (u, ind)
    write (u, 2) "branching ratio =", object%weight * 100
    call write_indent (u, ind)
    write (u, 1) "partial width  =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs)    =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel)     =", object%rel_error
1   format (3x,A,ES19.12)
2   format (3x,A,F11.6,1x,'%')
    call object%write_terms (unit, indent, verbose)
  end subroutine decay_config_write

```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should

be used instead.

```

<Decays: decay config: TBP>+≡
    procedure :: connect => decay_config_connect

<Decays: procedures>+≡
    recursive subroutine decay_config_connect &
        (decay, process, model, process_stack, process_instance)
        class(decay_config_t), intent(out) :: decay
        type(process_t), intent(in), target :: process
        class(model_data_t), intent(in), target :: model
        type(process_stack_t), intent(in), optional :: process_stack
        type(process_instance_t), intent(in), optional, target :: process_instance
        real(default), dimension(:), allocatable :: integral_mci
        integer :: i, n_mci
        call decay%decay_root_config_t%connect (process, model, process_stack)
        decay%integral = process%get_integral ()
        decay%abs_error = process%get_error ()
        if (process%cm_frame ()) then
            call msg_fatal ("Decay process " // char (process%get_id ()) &
                // ": unusable because rest frame is fixed.")
        end if
        n_mci = process%get_n_mci ()
        allocate (integral_mci (n_mci))
        do i = 1, n_mci
            integral_mci(i) = process%get_integral_mci (i)
        end do
        call decay%mci_selector%init (integral_mci)
    end subroutine decay_config_connect

```

Compute embedded branchings and the relative error. This method does not apply to the decay root.

```

<Decays: decay config: TBP>+≡
    procedure :: compute => decay_config_compute

<Decays: procedures>+≡
    recursive subroutine decay_config_compute (decay)
        class(decay_config_t), intent(inout) :: decay
        call decay%decay_root_config_t%compute ()
        if (decay%integral == 0) then
            call decay%write ()
            call msg_fatal ("Decay configuration: partial width is zero")
        end if
        decay%rel_error = decay%abs_error / decay%integral
    end subroutine decay_config_compute

```

30.2.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the decay is evaluated. This is similar to the decay root, but we implement it independently.

The process instance object is allocated via a pointer, so it automatically behaves as a target.

```

<Decays: types>+≡

```

```

type, extends (decay_gen_t) :: decay_t
  type(decay_config_t), pointer :: config => null ()
  class(rng_t), allocatable :: rng
contains
  <Decays: decay: TBP>
end type decay_t

```

The finalizer is recursive.

```

<Decays: decay: TBP>≡
  procedure :: final => decay_final

<Decays: procedures>+≡
  recursive subroutine decay_final (object)
    class(decay_t), intent(inout) :: object
    integer :: i
    call object%base_final ()
    do i = 1, object%config%process%get_n_mci ()
      call object%process_instance%final_simulation (i)
    end do
    call object%process_instance%final ()
    deallocate (object%process_instance)
  end subroutine decay_final

```

Output.

```

<Decays: decay: TBP>+≡
  procedure :: write => decay_write

<Decays: procedures>+≡
  recursive subroutine decay_write (object, unit, indent, recursive)
    class(decay_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent, recursive
    integer :: u, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call object%config%write (unit, indent, verbose = .false.)
    if (allocated (object%rng)) then
      call object%rng%write (u, ind + 1)
    end if
    call write_indent (u, ind)
    if (object%selected_mci > 0) then
      write (u, "(3x,A,I0)") "Selected MCI    = ", object%selected_mci
    else
      write (u, "(3x,A)") "Selected MCI    = [undefined]"
    end if
    call write_indent (u, ind)
    if (object%selected_term > 0) then
      write (u, "(3x,A,I0)") "Selected term  = ", object%selected_term
      call object%term(object%selected_term)%write (u, ind + 1)
    else
      write (u, "(3x,A)") "Selected term  = [undefined]"
    end if
  end subroutine decay_write

```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

```

<Decays: decay: TBP>+≡
  procedure :: init => decay_init

<Decays: procedures>+≡
  recursive subroutine decay_init (decay, config)
    class(decay_t), intent(out) :: decay
    type(decay_config_t), intent(in), target :: config
    integer :: i
    call decay%base_init (config%term_config)
    decay%config => config
    allocate (decay%process_instance)
    call decay%process_instance%init (decay%config%process)
    call decay%process_instance%setup_event_data (decay%config%model)
    do i = 1, decay%config%process%get_n_mci ()
      call decay%process_instance%init_simulation (i)
    end do
    call decay%config%process%make_rng (decay%rng)
    call decay%make_term_rng (decay%config%process)
  end subroutine decay_init

```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

```

<Decays: decay: TBP>+≡
  procedure :: link_interactions => decay_link_interactions

<Decays: procedures>+≡
  recursive subroutine decay_link_interactions (decay, i_prt, trace)
    class(decay_t), intent(inout) :: decay
    integer, intent(in) :: i_prt
    type(interaction_t), intent(in), target :: trace
    type(interaction_t), pointer :: beam_int
    integer :: n_in, n_vir
    beam_int => decay%process_instance%get_beam_int_ptr ()
    n_in = interaction_get_n_in (trace)
    n_vir = interaction_get_n_vir (trace)
    call interaction_set_source_link (beam_int, 1, trace, &
      n_in + n_vir + i_prt)
    call decay%link_term_interactions ()
  end subroutine decay_link_interactions

```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

```

<Decays: decay: TBP>+≡
  procedure :: select_chain => decay_select_chain

```

```

<Decays: procedures>+≡
recursive subroutine decay_select_chain (decay)
  class(decay_t), intent(inout) :: decay
  real(default) :: x
  integer :: i
  call decay%rng%generate (x)
  decay%selected_mci = decay%config%mc_selector%select (x)
  call decay%process_instance%choose_mci (decay%selected_mci)
  call decay%process_instance%select_i_term (decay%selected_term)
  do i = 1, size (decay%term)
    call decay%term(i)%select_chain ()
  end do
end subroutine decay_select_chain

```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

```

<Decays: decay: TBP>+≡
procedure :: generate => decay_generate

<Decays: procedures>+≡
recursive subroutine decay_generate (decay)
  class(decay_t), intent(inout) :: decay
  type(isolated_state_t), pointer :: isolated_state
  integer :: i
  call decay%process_instance%receive_beam_momenta ()
  call decay%config%process%generate_unweighted_event &
    (decay%process_instance, decay%selected_mci)
  if (signal_is_pending ()) return
  call decay%process_instance%evaluate_event_data ()
  isolated_state => &
    decay%process_instance%get_isolated_state_ptr (decay%selected_term)
  call isolated_state%normalize_matrix_by_trace ()
  do i = 1, size (decay%term)
    call decay%term(i)%generate ()
    if (signal_is_pending ()) return
  end do
end subroutine decay_generate

```

30.2.9 Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

```

<Decays: types>+≡
type, extends (any_config_t) :: stable_config_t
  type(flavor_t), dimension(:), allocatable :: flv
contains
  <Decays: stable config: TBP>

```

```
end type stable_config_t
```

The finalizer is empty:

```
<Decays: stable config: TBP>≡
  procedure :: final => stable_config_final

<Decays: procedures>+≡
  subroutine stable_config_final (object)
    class(stable_config_t), intent(inout) :: object
  end subroutine stable_config_final
```

Output.

```
<Decays: stable config: TBP>+≡
  procedure :: write => stable_config_write

<Decays: procedures>+≡
  recursive subroutine stable_config_write (object, unit, indent, verbose)
    class(stable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A)", advance = "no") "Stable:"
    write (u, "(1x,A)", advance = "no") char (flavor_get_name (object%flv(1)))
    do i = 2, size (object%flv)
      write (u, "(:',A)", advance = "no") &
        char (flavor_get_name (object%flv(i)))
    end do
    write (u, *)
  end subroutine stable_config_write
```

Initializer. We are presented with an array of flavors, but there may be double entries which we remove, so we store only the distinct flavors.

```
<Decays: stable config: TBP>+≡
  procedure :: init => stable_config_init

<Decays: procedures>+≡
  subroutine stable_config_init (config, flv)
    class(stable_config_t), intent(out) :: config
    type(flavor_t), dimension(:), intent(in) :: flv
    integer, dimension (size (flv)) :: pdg
    logical, dimension (size (flv)) :: mask
    integer :: i

```

Initializer: just assign the configuration.

```

<Decays: stable: TBP>+≡
  procedure :: init => stable_init

<Decays: procedures>+≡
  subroutine stable_init (stable, config)
    class(stable_t), intent(out) :: stable
    type(stable_config_t), intent(in), target :: config
    stable%config => config
  end subroutine stable_init

```

30.2.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

```

<Decays: types>+≡
  type, extends (any_config_t) :: unstable_config_t
    type(flavor_t) :: flv

```

```

    real(default) :: integral = 0
    real(default) :: abs_error = 0
    real(default) :: rel_error = 0
    type(selector_t) :: selector
    type(decay_config_t), dimension(:), allocatable :: decay_config
contains
  <Decays: unstable config: TBP>
end type unstable_config_t

```

Finalizer. The branching configuration can be a recursive structure.

```

<Decays: unstable config: TBP>≡
  procedure :: final => unstable_config_final

<Decays: procedures>+≡
  recursive subroutine unstable_config_final (object)
    class(unstable_config_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%final ()
      end do
    end if
  end subroutine unstable_config_final

```

Output. Since this may be recursive, we include indentation.

```

<Decays: unstable config: TBP>+≡
  procedure :: write => unstable_config_write

<Decays: procedures>+≡
  recursive subroutine unstable_config_write (object, unit, indent, verbose)
    class(unstable_config_t), intent(in) :: object
    integer, intent(in), optional :: unit, indent
    logical, intent(in), optional :: verbose
    integer :: u, i, ind
    logical :: verb
    u = given_output_unit (unit)
    ind = 0; if (present (indent)) ind = indent
    verb = .true.; if (present (verbose)) verb = verbose
    call write_indent (u, ind)
    write (u, "(1x,'+',1x,A,1x,A)") "Unstable:", &
      char (flavor_get_name (object%flv))
    call write_indent (u, ind)
    write (u, 1) "total width =", object%integral
    call write_indent (u, ind)
    write (u, 1) "error (abs) =", object%abs_error
    call write_indent (u, ind)
    write (u, 1) "error (rel) =", object%rel_error
1  format (5x,A,ES19.12)
    if (verb .and. allocated (object%decay_config)) then
      do i = 1, size (object%decay_config)
        call object%decay_config(i)%write (u, ind + 1)
      end do
    end if
  end subroutine unstable_config_write

```

Initializer. For the unstable particle, the flavor is unique.

```

<Decays: unstable config: TBP>+≡
  procedure :: init => unstable_config_init

<Decays: procedures>+≡
  subroutine unstable_config_init (config, flv)
    class(unstable_config_t), intent(out) :: config
    type(flavor_t), intent(in) :: flv
    config%flv = flv
  end subroutine unstable_config_init

```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

```

<Decays: unstable config: TBP>+≡
  procedure :: init_decays => unstable_config_init_decays

<Decays: procedures>+≡
  recursive subroutine unstable_config_init_decays &
    (unstable, decay_id, model, process_stack)
    class(unstable_config_t), intent(inout) :: unstable
    type(string_t), dimension(:), intent(in) :: decay_id
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    integer :: i
    allocate (unstable%decay_config (size (decay_id)))
    do i = 1, size (decay_id)
      associate (decay => unstable%decay_config(i))
        if (present (process_stack)) then
          call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
            model, process_stack)
        else
          call decay%init (model, decay_id(i))
        end if
      end associate
    end do
  end subroutine unstable_config_init_decays

```

Compute the total width and branching ratios, initializing the decay selector.

```

<Decays: unstable config: TBP>+≡
  procedure :: compute => unstable_config_compute

<Decays: procedures>+≡
  recursive subroutine unstable_config_compute (unstable)
    class(unstable_config_t), intent(inout) :: unstable
    integer :: i
    do i = 1, size (unstable%decay_config)
      call unstable%decay_config(i)%compute ()
    end do
    unstable%integral = sum (unstable%decay_config%integral)
    if (unstable%integral <= 0) then

```

```

        call unstable%write ()
        call msg_fatal ("Decay configuration: computed total width is zero")
    end if
    unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
    unstable%rel_error = unstable%abs_error / unstable%integral
    call unstable%selector%init (unstable%decay_config%integral)
    do i = 1, size (unstable%decay_config)
        unstable%decay_config(i)%weight &
            = unstable%selector%get_weight (i)
    end do
end subroutine unstable_config_compute

```

Now we define the instance of an unstable particle.

```

<Decays: types>+≡
type, extends (any_t) :: unstable_t
    type(unstable_config_t), pointer :: config => null ()
    class(rng_t), allocatable :: rng
    integer :: selected_decay = 0
    type(decay_t), dimension(:), allocatable :: decay
contains
    <Decays: unstable: TBP>
end type unstable_t

```

Recursive finalizer.

```

<Decays: unstable: TBP>≡
    procedure :: final => unstable_final

<Decays: procedures>+≡
recursive subroutine unstable_final (object)
    class(unstable_t), intent(inout) :: object
    integer :: i
    if (allocated (object%decay)) then
        do i = 1, size (object%decay)
            call object%decay(i)%final ()
        end do
    end if
end subroutine unstable_final

```

Output.

```

    procedure :: generate => unstable_generate

<Decays: procedures>+≡
    recursive subroutine unstable_generate (unstable)
        class(unstable_t), intent(inout) :: unstable
        call unstable%decay(unstable%selected_decay)%generate ()
    end subroutine unstable_generate

```

30.2.11 Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle

decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

```

<Decays: types>+≡
  type, extends (connected_state_t) :: decay_chain_entry_t
    integer :: index = 0
    type(decay_config_t), pointer :: config => null ()
    integer :: selected_mci = 0
    integer :: selected_term = 0
    type(decay_chain_entry_t), pointer :: previous => null ()
  end type decay_chain_entry_t

```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

```

<Decays: types>+≡
  type :: decay_chain_t
    type(process_instance_t), pointer :: process_instance => null ()
    integer :: selected_term = 0
    type(evaluator_t) :: correlated_trace
    type(decay_chain_entry_t), pointer :: last => null ()
  contains
    <Decays: decay_chain: TBP>
  end type decay_chain_t

```

The finalizer recursively deletes and deallocates the entries.

```

<Decays: decay_chain: TBP>≡
  procedure :: final => decay_chain_final

<Decays: procedures>+≡
  subroutine decay_chain_final (object)
    class(decay_chain_t), intent(inout) :: object
    type(decay_chain_entry_t), pointer :: entry
    do while (associated (object%last))
      entry => object%last
      object%last => entry%previous
      call entry%final ()
      deallocate (entry)
    end do
    call evaluator_final (object%correlated_trace)
  end subroutine decay_chain_final

```

Doing output recursively allows us to display the chain in chronological order.

```

<Decays: decay chain: TBP>+≡
  procedure :: write => decay_chain_write

<Decays: procedures>+≡
  subroutine decay_chain_write (object, unit)
    class(decay_chain_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u
    u = given_output_unit (unit)
    call write_separator (u, 2)
    write (u, "(1x,A)") "Decay chain:"
    call write_entries (object%last)
    call write_separator (u, 2)
    write (u, "(1x,A)") "Evaluator (correlated trace of the decay chain):"
    call write_separator (u)
    call object%correlated_trace%write (u)
    call write_separator (u, 2)
contains
  recursive subroutine write_entries (entry)
    type(decay_chain_entry_t), intent(in), pointer :: entry
    if (associated (entry)) then
      call write_entries (entry%previous)
      call write_separator (u, 2)
      write (u, "(1x,A,I0)") "Decay #", entry%index
      call entry%config%write_header (u)
      write (u, "(3x,A,I0)") "Selected MCI    = ", entry%selected_mci
      write (u, "(3x,A,I0)") "Selected term  = ", entry%selected_term
      call entry%config%term_config(entry%selected_term)%write (u, indent=1)
      call entry%write (u)
    end if
  end subroutine write_entries
end subroutine decay_chain_write

```

Build a decay chain, recursively following the selected decays and terms in a decay tree. Before start, we finalize the chain, deleting any previous contents.

```

<Decays: decay chain: TBP>+≡
  procedure :: build => decay_chain_build

<Decays: procedures>+≡
  subroutine decay_chain_build (chain, decay_root)
    class(decay_chain_t), intent(inout), target :: chain
    type(decay_root_t), intent(in) :: decay_root
    type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
    type(interaction_t), pointer :: int_last_decay
    call chain%final ()
    if (decay_root%selected_term > 0) then
      chain%process_instance => decay_root%process_instance
      chain%selected_term = decay_root%selected_term
      call chain%build_term_entries (decay_root%term(decay_root%selected_term))
    end if
    int_last_decay => chain%last%get_matrix_int_ptr ()
    allocate (qn_mask (interaction_get_n_tot (int_last_decay)))

```

```

    call quantum_numbers_mask_init (qn_mask, &
        mask_f = .true., mask_c = .true., mask_h = .true.)
    call evaluator_init_qn_sum (chain%correlated_trace, int_last_decay, qn_mask)
end subroutine decay_chain_build

```

Build the entries that correspond to a decay term. We have to scan all unstable particles.

```

<Decays: decay chain: TBP>+≡
    procedure :: build_term_entries => decay_chain_build_term_entries

<Decays: procedures>+≡
    recursive subroutine decay_chain_build_term_entries (chain, term)
        class(decay_chain_t), intent(inout) :: chain
        type(decay_term_t), intent(in) :: term
        integer :: i
        do i = 1, size (term%particle_out)
            select type (unstable => term%particle_out(i)%c)
                type is (unstable_t)
                    if (unstable%selected_decay > 0) then
                        call chain%build_decay_entries &
                            (unstable%decay(unstable%selected_decay))
                    end if
                end select
            end do
        end subroutine decay_chain_build_term_entries

```

Build the entries that correspond to a specific decay. The decay term should have been determined, so we allocate a decay chain entry and fill it, then proceed to child decays.

For the first entry, we convolute the connected state of the parent process instance with the isolated state of the current decay (which does not contain an extra beam entry for the parent). For subsequent entries, we take the previous entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a subevent object and associated expressions. We currently do not make use of that feature.

Before generating the decays, factor out the trace of the helicity density matrix of the parent parton state. This trace has been used for unweighting the original event (unweighted case) or it determines the overall weight, so it should not be taken into account in the decay chain generation.

```

<Decays: decay chain: TBP>+≡
    procedure :: build_decay_entries => decay_chain_build_decay_entries

<Decays: procedures>+≡
    recursive subroutine decay_chain_build_decay_entries (chain, decay)
        class(decay_chain_t), intent(inout) :: chain
        type(decay_t), intent(in) :: decay
        type(decay_chain_entry_t), pointer :: entry
        type(connected_state_t), pointer :: previous_state
        type(isolated_state_t), pointer :: current_decay
        allocate (entry)
        if (associated (chain%last)) then

```

```

        entry%previous => chain%last
        entry%index = entry%previous%index + 1
        previous_state => entry%previous%connected_state_t
    else
        entry%index = 1
        previous_state => &
            chain%process_instance%get_connected_state_ptr (chain%selected_term)
    end if
    entry%config => decay%config
    entry%selected_mci = decay%selected_mci
    entry%selected_term = decay%selected_term
    current_decay => decay%process_instance%get_isolated_state_ptr &
        (decay%selected_term)
    call entry%setup_connected_trace &
        (current_decay, previous_state%get_trace_int_ptr (), resonant=.true.)
    call entry%setup_connected_matrix &
        (current_decay, previous_state%get_matrix_int_ptr (), resonant=.true.)
    call entry%setup_connected_flows &
        (current_decay, previous_state%get_flows_int_ptr (), resonant=.true.)
    chain%last => entry
    call chain%build_term_entries (decay%term(decay%selected_term))
end subroutine decay_chain_build_decay_entries

```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

```

<Decays: decay chain: TBP>+≡
    procedure :: evaluate => decay_chain_evaluate

<Decays: procedures>+≡
    subroutine decay_chain_evaluate (chain)
        class(decay_chain_t), intent(inout) :: chain
        call evaluate (chain%last)
        call evaluator_receive_momenta (chain%correlated_trace)
        call chain%correlated_trace%evaluate ()
    contains
        recursive subroutine evaluate (entry)
            type(decay_chain_entry_t), intent(inout), pointer :: entry
            if (associated (entry)) then
                call evaluate (entry%previous)
                call entry%receive_kinematics ()
                call entry%evaluate_trace ()
                call entry%evaluate_event_data ()
            end if
        end subroutine evaluate
    end subroutine decay_chain_evaluate

```

Return the probability of a decay chain. This is given as the trace of the density matrix with intermediate helicity correlations, normalized by the product of the uncorrelated density matrix traces. This works only if an event has been

evaluated and the `correlated_trace` evaluator is filled. By definition, this evaluator has only one matrix element, and this must be real.

```

<Decays: decay chain: TBP>+≡
  procedure :: get_probability => decay_chain_get_probability

<Decays: procedures>+≡
  function decay_chain_get_probability (chain) result (x)
    class(decay_chain_t), intent(in) :: chain
    real(default) :: x
    x = evaluator_get_matrix_element (chain%correlated_trace, 1)
  end function decay_chain_get_probability

```

30.2.12 Decay as Event Transform

The `evt_decay` object combines decay configuration, decay tree, and chain in a single object, as an implementation of the `evt` (event transform) abstract type.

```

<Decays: public>≡
  public :: evt_decay_t

<Decays: types>+≡
  type, extends (evt_t) :: evt_decay_t
    type(decay_root_config_t) :: decay_root_config
    type(decay_root_t) :: decay_root
    type(decay_chain_t) :: decay_chain
  contains
    <Decays: evt decay: TBP>
  end type evt_decay_t

```

Output. We display the currently selected decay tree, which includes configuration data, and the decay chain, i.e., the evaluators.

```

<Decays: evt decay: TBP>≡
  procedure :: write => evt_decay_write

<Decays: procedures>+≡
  subroutine evt_decay_write (object, unit, &
    show_decay_tree, &
    show_processes, &
    verbose)
    class(evt_decay_t), intent(in) :: object
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: show_decay_tree, show_processes, verbose
    logical :: dec, prc, verb
    integer :: u
    u = given_output_unit (unit)

Connect with a process instance and process. This initializes the decay configuration. The process stack is used to look for process objects that implement daughter decays.

When all processes are assigned, configure the decay tree instance, using the decay tree configuration. First obtain the branching ratios, then allocate the decay tree. This is done once for all events.

```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations might be useful. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid.

Matching and hadronization functions

The HEPUP (event) common block is needed for the interface to the shower. Filling of it is triggered by some output file formats. If these are not present, the common block is filled with some dummy information. Be generous with the number of processes in HEPUP so that PYTHIA only rarely needs to be reinitialized in case events with higher process ids are generated.

    <Events: parameters>  
  
    <Events: types>  
  
    <Events: interfaces>  
  
    contains  
  
    <Events: procedures>  
  
    <Events: tests>  
  
  end module events
```

30.4.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The `safety_factor` reduces the acceptance probability for unweighting. If

greater than one, excess events become less likely, but the reweighting efficiency also drops.

The `sigma` and `n` values, if nontrivial, allow for reweighting the events according to the requested `norm_mode`.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the `event_expr_t` objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

```

<Events: types>≡
  type :: event_config_t
    logical :: unweighted = .false.
    integer :: norm_mode = NORM_UNDEFINED
    integer :: factorization_mode = FM_IGNORE_HELICITY
    logical :: keep_correlations = .false.

30.4.2 Event normalization

The parameters for event normalization. For unweighted events, `NORM_UNIT` is intended as default, while for weighted events, it is `NORM_SIGMA`.

Note: the unit test for this is in `eio_data_2` below.

(Events: parameters)≡

```

integer, parameter, public :: NORM_UNDEFINED = 0
integer, parameter, public :: NORM_UNIT = 1
integer, parameter, public :: NORM_N_EVT = 2
integer, parameter, public :: NORM_SIGMA = 3
integer, parameter, public :: NORM_S_N = 4

```

These functions translate between the user representation and the internal one.

(Events: public)≡

```

public :: event_normalization_mode
public :: event_normalization_string

```

(Events: procedures)+≡

```

function event_normalization_mode (string, unweighted) result (mode)
    integer :: mode
    type(string_t), intent(in) :: string
    logical, intent(in) :: unweighted
    select case (lower_case (char (string)))
    case ("auto")
        if (unweighted) then
            mode = NORM_UNIT
        else
            mode = NORM_SIGMA
        end if
    case ("1")
        mode = NORM_UNIT
    case ("1/n")

```

```

        mode = NORM_N_EVT
    case ("sigma")
        mode = NORM_SIGMA
    case ("sigma/n")
        mode = NORM_S_N
    case default
        call msg_fatal ("Event normalization: unknown value '" &
            // char (string) // "'")
    end select
end function event_normalization_mode

function event_normalization_string (norm_mode) result (string)
    integer, intent(in) :: norm_mode
    type(string_t) :: string
    select case (norm_mode)
    case (NORM_UNDEFINED); string = "[undefined]"
    case (NORM_UNIT);      string = "'1'"
    case (NORM_N_EVT);     string = "'1/n'"
    case (NORM_SIGMA);     string = "'sigma'"
    case (NORM_S_N);       string = "'sigma/n'"
    case default;          string = "???"
    end select
end function event_normalization_string

```

We place this here as a generic helper, so we can update event weights whenever we need, not just in connection with an event sample data object.

```

<Events: public>+≡
    public :: event_normalization_update

<Events: procedures>+≡
    subroutine event_normalization_update (weight, sigma, n, mode_new, mode_old)

            end select
        end function factor
    end subroutine event_normalization_update

```

```

end function factor
end subroutine event_normalization_update

```

30.4.3 The event type

Each event has a single elementary process as its core. This process may be dressed by a shower, a decay chain etc. For this core we implement pointers to a process instance.

The actual (dressed) event record is implemented as a `particle_set` object.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

The `sqme` and `weight` values mirror corresponding values in the `expr` subobject. The idea is that when generating or reading events, the event record is filled first, then the `expr` object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the `expr` subobject. In particular, evaluating the event-selection expression sets the `passed` flag. Furthermore, the `expr` subobject collects data that can be used in the analysis and should be written to file, including copies of `sqme` and `weight`.

```

30.4.4 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this `init`, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

(Events: event: TBP)+≡

```

    procedure :: basic_init => event_init

```

(Events: procedures)+≡

```

    subroutine event_init (event, var_list, n_alt)
        class(event_t), intent(out) :: event
        type(var_list_t), intent(in), optional :: var_list
        integer, intent(in), optional :: n_alt
        type(string_t) :: norm_string

```

```

logical :: polarized_events
if (present (var_list)) then
  event%config%unweighted = var_list_get_lval (var_list, &
    var_str ("?unweighted"))
  norm_string = var_list_get_sval (var_list, &
    var_str ("sample_normalization"))
  event%config%norm_mode = &
    event_normalization_mode (norm_string, event%config%unweighted)
  polarized_events = &
    var_list_get_lval (var_list, var_str ("?polarized_events"))
  if (polarized_events) then
    event%config%factorization_mode = FM_SELECT_HELICITY
  else
    event%config%factorization_mode = FM_IGNORE_HELICITY
  end if
  if (event%config%unweighted) then
    event%config%safety_factor = var_list_get_rval (var_list, &
      var_str ("safety_factor"))
  end if
else
  event%config%norm_mode = NORM_SIGMA
end if
if (present (n_alt)) then
  event%n_alt = n_alt
  allocate (event%sqme_alt (n_alt))
  allocate (event%weight_alt (n_alt))
  call event%expr%init (n_alt)
end if
allocate (evt_trivial_t :: event%transform_first)
event%transform_last => event%transform_first
end subroutine event_init

```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

(Events: event: TBP)+≡

```

procedure :: set_sigma => event_set_sigma
procedure :: set_n => event_set_n

```

(Events: procedures)+≡

```

elemental subroutine event_set_sigma (event, sigma)
  class(event_t), intent(inout) :: event
  real(default), intent(in) :: sigma
  event%config%sigma = sigma
end subroutine event_set_sigma

elemental subroutine event_set_n (event, n)
  class(event_t), intent(inout) :: event
  integer, intent(in) :: n
  event%config%n = n
end subroutine event_set_n

```

Append an event transform (decays, etc.). The transform is not yet connected

to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

```

<Events: event: TBP>+≡
  procedure :: import_transform => event_import_transform

<Events: procedures>+≡
  subroutine event_import_transform (event, evt)
    class(event_t), intent(inout) :: event
    class(evt_t), intent(inout), pointer :: evt
    event%transform_last%next => evt
    evt%previous => event%transform_last
    event%transform_last => evt
    evt => null ()
  end subroutine event_import_transform

```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to **event** subobjects, therefore the **target** attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

```

<Events: event: TBP>+≡
  procedure :: connect => event_connect

<Events: procedures>+≡
  subroutine event_connect (event, process_instance, model, process_stack)
    class(event_t), intent(inout), target :: event
    type(process_instance_t), intent(in), target :: process_instance
    class(model_data_t), intent(in), target :: model
    type(process_stack_t), intent(in), optional :: process_stack
    type(string_t) :: id
    integer :: num_id
    class(evt_t), pointer :: evt
    event%process => process_instance%process
    event%instance => process_instance
    id = event%process%get_id ()
    if (id /= "") call event%expr%set_process_id (id)
    num_id = event%process%get_num_id ()
    if (num_id /= 0) call event%expr%set_process_num_id (num_id)
    call event%expr%setup_vars (event%process%get_sqrts ())
    call event%expr%link_var_list (event%process%get_var_list_ptr ())
    call event%process%make_rng (event%rng)
    evt => event%transform_first
    do while (associated (evt))
      call evt%connect (process_instance, model, process_stack)
      evt => evt%next
    end do
  end subroutine event_connect

```

```

        end do
    end subroutine event_connect

```

Set the parse nodes for the associated expressions, individually. The parse-node pointers may be null.

```

<Events: event: TBP>+≡
    procedure :: set_selection => event_set_selection
    procedure :: set_reweight => event_set_reweight
    procedure :: set_analysis => event_set_analysis

<Events: procedures>+≡
    subroutine event_set_selection (event, ef_selection)
        class(event_t), intent(inout) :: event
        class(expr_factory_t), intent(in) :: ef_selection
        allocate (event%config%ef_selection, source = ef_selection)
    end subroutine event_set_selection

    subroutine event_set_reweight (event, ef_reweight)
        class(event_t), intent(inout) :: event
        class(expr_factory_t), intent(in) :: ef_reweight
        allocate (event%config%ef_reweight, source = ef_reweight)
    end subroutine event_set_reweight

    subroutine event_set_analysis (event, ef_analysis)
        class(event_t), intent(inout) :: event
        class(expr_factory_t), intent(in) :: ef_analysis
        allocate (event%config%ef_analysis, source = ef_analysis)
    end subroutine event_set_analysis

```

Create evaluation trees from the parse trees. The `target` attribute is required because the expressions contain pointers to event subobjects.

```

<Events: event: TBP>+≡
    procedure :: setup_expressions => event_setup_expressions

<Events: procedures>+≡
    subroutine event_setup_expressions (event)
        class(event_t), intent(inout), target :: event
        call event%expr%setup_selection (event%config%ef_selection)
        call event%expr%setup_analysis (event%config%ef_analysis)
        call event%expr%setup_reweight (event%config%ef_reweight)
    end subroutine event_setup_expressions

```

30.4.5 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all event transforms in order. The last transform should fill its associated particle set, factorizing the state matrix according to the current settings. There are several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to

be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

(Events: event: TBP)+≡

```
procedure :: evaluate_transforms => event_evaluate_transforms
```

(Events: procedures)+≡

```
subroutine event_evaluate_transforms (event, r)
  class(event_t), intent(inout) :: event
  real(default), dimension(:), intent(in), optional :: r
  class(evt_t), pointer :: evt
  integer :: i_term
  event%particle_set_exists = .false.
  call event%check ()
  if (event%instance%is_complete_event ()) then
    call event%instance%select_i_term (i_term)
    event%selected_i_term = i_term
    evt => event%transform_first
    do while (associated (evt))
      call evt%prepare_new_event &
        (event%selected_i_mci, event%selected_i_term)
      evt => evt%next
    end do
    evt => event%transform_first
    do while (associated (evt))
      call evt%generate_unweighted ()
      if (signal_is_pending ()) return
      call evt%make_particle_set (event%config%factorization_mode, &
        event%config%keep_correlations)
      if (signal_is_pending ()) return
      if (.not. evt%particle_set_exists) exit
      evt => evt%next
    end do
    evt => event%transform_last
    if (associated (evt) .and. evt%particle_set_exists) then
      event%particle_set => evt%particle_set
      call event%accept_particle_set ()
    end if
  end if
end subroutine event_evaluate_transforms
```

Evaluate the event-related expressions, given a valid `particle_set`. If `update_sqme` is set, we use the process instance for the `sqme_prc` value. The `sqme_ref` value is always taken from the event record.

(Events: event: TBP)+≡

```
procedure :: evaluate_expressions => event_evaluate_expressions
```

(Events: procedures)+≡

```
subroutine event_evaluate_expressions (event)
  class(event_t), intent(inout) :: event
  if (event%particle_set_exists) then

    end if
end subroutine event_check

```

30.4.8 Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we **accept** the latter.

The explicit random number argument **r** should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

```

<Events: event: TBP>+≡
    procedure :: generate => event_generate

<Events: procedures>+≡
    subroutine event_generate (event, i_mci, r)
        class(event_t), intent(inout) :: event
        integer, intent(in) :: i_mci
        real(default), dimension(:), intent(in), optional :: r
        call event%reset ()
        event%selected_i_mci = i_mci
        if (event%config%unweighted) then
            call event%process%generate_unweighted_event (event%instance, i_mci)
            if (signal_is_pending ()) return
            call event%instance%evaluate_event_data ()
            call event%instance%normalize_weight ()
        else
            call event%process%generate_weighted_event (event%instance, i_mci)
            if (signal_is_pending ()) return
            call event%instance%evaluate_event_data ()

        call event%update_normalization ()
        call event%accept_weight_prc ()
        call event%evaluate_transforms (r)
        if (signal_is_pending ()) return
        call event%check ()
    end subroutine event_generate

```

Get a copy of the particle set belonging to the hard process.

```

<Events: event: TBP>+≡
  procedure :: get_particle_set_hard_proc => event_get_particle_set_hard_proc

<Events: procedures>+≡
  subroutine event_get_particle_set_hard_proc (event, pset)
    class(event_t), intent(in) :: event
    type(particle_set_t), intent(out) :: pset
    class(evt_t), pointer :: evt
    evt => event%transform_first
    pset = evt%particle_set
  end subroutine event_get_particle_set_hard_proc

```

30.4.9 Recovering an event

Select MC group, term, and integration channel.

```

<Events: event: TBP>+≡
  procedure :: select => event_select

<Events: procedures>+≡
  subroutine event_select (event, i_mci, i_term, channel)
    class(event_t), intent(inout) :: event
    integer, intent(in) :: i_mci, i_term, channel
    if (associated (event%instance)) then
      event%selected_i_mci = i_mci
      event%selected_i_term = i_term
      event%selected_channel = channel
    else
      call msg_bug ("Event: select term: process instance undefined")
    end if
  end subroutine event_select

```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. Thus, with the current implementation, event readers can only be used for reading hard events. However, once we have reconstructed the master process, we may apply all event transforms to generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

```

<Events: event: TBP>+≡
  procedure :: set_particle_set_hard_proc => event_set_particle_set_hard_proc

<Events: procedures>+≡
  subroutine event_set_particle_set_hard_proc (event, particle_set)
    class(event_t), intent(inout) :: event
    type(particle_set_t), intent(in) :: particle_set
    class(evt_t), pointer :: evt
    evt => event%transform_first
    call evt%set_particle_set (particle_set, &
      event%selected_i_mci, event%selected_i_term)
    event%particle_set => evt%particle_set
    call event%accept_particle_set ()
  end subroutine event_set_particle_set_hard_proc

```

```

    evt => evt%next
  do while (associated (evt))
    call evt%reset ()
    evt => evt%next
  end do
end subroutine event_set_particle_set_hard_proc

```

Mark the particle set as existing, assuming that it has just been filled somehow.

```

<Events: event: TBP>+≡
  procedure :: accept_particle_set => event_accept_particle_set

<Events: procedures>+≡
  subroutine event_accept_particle_set (event)
    class(event_t), intent(inout) :: event
    event%particle_set_exists = .true.
  end subroutine event_accept_particle_set

```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

```

<Events: event: TBP>+≡
  procedure :: recalculate => event_recalculate

<Events: procedures>+≡
  subroutine event_recalculate &
    (event, update_sqme, weight_factor, recover_beams)
    class(event_t), intent(inout) :: event

```

30.4.10 Access content

Pointer to the associated process object.

```

<Events: event: TBP>+≡
  procedure :: get_process_ptr => event_get_process_ptr

<Events: procedures>+≡
  function event_get_process_ptr (event) result (ptr)
    class(event_t), intent(in) :: event
    type(process_t), pointer :: ptr
    ptr => event%process
  end function event_get_process_ptr

```

Tell whether the particle set is defined:

```

<Events: event: TBP>+≡
  procedure :: has_particle_set => event_has_particle_set

<Events: procedures>+≡
  function event_has_particle_set (event) result (flag)
    class(event_t), intent(in) :: event
    logical :: flag
    flag = event%particle_set_exists

```

```
end function event_has_particle_set
```

Pointer to the particle set.

```
<Events: event: TBP>+≡
  procedure :: get_particle_set_ptr => event_get_particle_set_ptr

<Events: procedures>+≡
  function event_get_particle_set_ptr (event) result (ptr)
    class(event_t), intent(in), target :: event
    type(particle_set_t), pointer :: ptr
    ptr => event%particle_set
  end function event_get_particle_set_ptr
```

Return the current values of indices: the MCI group of components, the term index (different terms corresponding, potentially, to different effective kinematics), and the MC integration channel. The `i_mci` call is delegated to the current process instance.

```
<Events: event: TBP>+≡
  procedure :: get_i_mci => event_get_i_mci
  procedure :: get_i_term => event_get_i_term
  procedure :: get_channel => event_get_channel

Chapter 31

Matrix Element Implementations

In this chapter, we define concrete implementations for the workflow, from matrix-element code generation via matrix-element access to integration and event generation.

31.1 Template matrix elements

Here, we provide template matrix elements that are in structure very similar to O'MEGA matrix elements, but do not need its infrastructure. Per default, the matrix elements are flat, i.e. they have the constant value one. Analogous to the O'MEGA implementation, this section implements the interface to the templates (via the makefile) and the driver.

```
<prc_template_me.f90>≡  
  <File header>  
  
  module prc_template_me  
  
    use iso_c_binding !NODEP!  
    use kinds  
    use io_units  
    <Use strings>  
    use unit_tests  
    use system_defs, only: TAB  
    use diagnostics  
    use os_interface  
    use lorentz  
    use flavors  
    use sm_qcd  
    use interactions  
    use variables  
    use model_data  
    use models  
  
    use process_constants
```

```

    use prclib_interfaces
    use prc_core_def
    use particle_specifiers
    use process_libraries
    use prc_core

    <Standard module head>

    <Template matrix elements: public>

    <Template matrix elements: types>

    <Template matrix elements: interfaces>

    contains

    <Template matrix elements: procedures>

    <Template matrix elements: tests>

    end module prc_template_me

```

31.1.1 Process definition

For the process definition we implement an extension of the `prc_core_def_t` abstract type.

```

<Template matrix elements: public>≡
    public :: template_me_def_t

<Template matrix elements: types>≡
    type, extends (prc_core_def_t) :: template_me_def_t
    contains
    <Template matrix elements: template ME def: TBP>
    end type template_me_def_t

<Template matrix elements: template ME def: TBP>≡
    procedure, nopass :: type_string => template_me_def_type_string

<Template matrix elements: procedures>≡
    function template_me_def_type_string () result (string)
        type(string_t) :: string
        string = "template"
    end function template_me_def_type_string

```

Initialization: allocate the writer for the template matrix element. Also set any data for this process that the writer needs.

```

<Template matrix elements: template ME def: TBP>+≡
    procedure :: init => template_me_def_init

<Template matrix elements: procedures>+≡
    subroutine template_me_def_init &
        (object, model, prt_in, prt_out, unity)
        class(template_me_def_t), intent(out) :: object
        type(model_t), intent(in), target :: model
    end subroutine

```

```

type(string_t), dimension(:), intent(in) :: prt_in
type(string_t), dimension(:), intent(in) :: prt_out
logical, intent(in) :: unity
allocate (template_me_writer_t :: object%writer)
select type (writer => object%writer)
type is (template_me_writer_t)
    call writer%init (model, prt_in, prt_out, unity)
end select
end subroutine template_me_def_init

```

Write/read process- and method-specific data.

```

<Template matrix elements: template ME def: TBP>+≡
    procedure :: write => template_me_def_write

```

```

<Template matrix elements: procedures>+≡
    subroutine template_me_def_write (object, unit)
        class(template_me_def_t), intent(in) :: object
        integer, intent(in) :: unit
        select type (writer => object%writer)
        type is (template_me_writer_t)
            call writer%write (unit)
        end select
    end subroutine template_me_def_write

```

```

<Template matrix elements: template ME def: TBP>+≡
    procedure :: read => template_me_def_read

```

```

<Template matrix elements: procedures>+≡
    subroutine template_me_def_read (object, unit)
        class(template_me_def_t), intent(out) :: object
        integer, intent(in) :: unit
        call msg_bug &
            ("WHIZARD template process definition: input not supported (yet)")
    end subroutine template_me_def_read

```

Allocate the driver for template matrix elements.

```

<Template matrix elements: template ME def: TBP>+≡
    procedure :: allocate_driver => template_me_def_allocate_driver

```

```

<Template matrix elements: procedures>+≡
    subroutine template_me_def_allocate_driver (object, driver, basename)
        class(template_me_def_t), intent(in) :: object
        class(prc_core_driver_t), intent(out), allocatable :: driver
        type(string_t), intent(in) :: basename
        allocate (template_me_driver_t :: driver)
    end subroutine template_me_def_allocate_driver

```

We need code:

```

<Template matrix elements: template ME def: TBP>+≡
    procedure, nopass :: needs_code => template_me_def_needs_code

```

```

<Template matrix elements: procedures>+≡
function template_me_def_needs_code () result (flag)
    logical :: flag
    flag = .true.
end function template_me_def_needs_code

```

These are the features that a template matrix element provides.

```

<Template matrix elements: template ME def: TBP>+≡
procedure, nopass :: get_features => template_me_def_get_features

<Template matrix elements: procedures>+≡
subroutine template_me_def_get_features (features)
    type(string_t), dimension(:), allocatable, intent(out) :: features
    allocate (features (6))
    features = [ &
        var_str ("init"), &
        var_str ("update_alpha_s"), &
        var_str ("is_allowed"), &
        var_str ("new_event"), &
        var_str ("get_amplitude")]
end subroutine template_me_def_get_features

```

The interface of the specific features.

```

<Template matrix elements: interfaces>≡
abstract interface
    subroutine init_t (par) bind(C)
        import
        real(c_default_float), dimension(*), intent(in) :: par
    end subroutine init_t
end interface

abstract interface
    subroutine update_alpha_s_t (alpha_s) bind(C)
        import
        real(c_default_float), intent(in) :: alpha_s
    end subroutine update_alpha_s_t
end interface

abstract interface
    subroutine is_allowed_t (flv, hel, col, flag) bind(C)
        import
        integer(c_int), intent(in) :: flv, hel, col
        logical(c_bool), intent(out) :: flag
    end subroutine is_allowed_t
end interface

abstract interface
    subroutine new_event_t (p) bind(C)
        import
        real(c_default_float), dimension(0:3,*), intent(in) :: p
    end subroutine new_event_t
end interface

```

```

abstract interface
  subroutine get_amplitude_t (flv, hel, col, amp) bind(C)
    import
    integer(c_int), intent(in) :: flv, hel, col
    complex(c_default_complex), intent(out):: amp
  end subroutine get_amplitude_t
end interface

```

Connect the template matrix element features with the process driver.

<Template matrix elements: template ME def: TBP>+≡

```

  procedure :: connect => template_me_def_connect

```

<Template matrix elements: procedures>+≡

```

  subroutine template_me_def_connect (def, lib_driver, i, proc_driver)
    class(template_me_def_t), intent(in) :: def
    class(prclib_driver_t), intent(in) :: lib_driver
    integer, intent(in) :: i
    class(prc_core_driver_t), intent(inout) :: proc_driver
    integer(c_int) :: pid, fid
    type(c_funptr) :: fptr
    select type (proc_driver)
    type is (template_me_driver_t)
      pid = i
      fid = 1
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%init)
      fid = 2
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%update_alpha_s)
      fid = 3
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%is_allowed)
      fid = 4
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%new_event)
      fid = 5
      call lib_driver%get_fptr (pid, fid, fptr)
      call c_f_procpointer (fptr, proc_driver%get_amplitude)
    end select
  end subroutine template_me_def_connect

```

31.1.2 The Template Matrix element writer

Unlike O'MEGA, the template matrix element is directly written by the main WHIZARD program, so there will be no entry in the makefile for calling an external program. The template matrix element writer is responsible for writing interfaces and wrappers.

<Template matrix elements: types>+≡

```

  type, extends (prc_writer_f_module_t) :: template_me_writer_t
    type(model_t), pointer :: model => null ()
    type(string_t) :: model_name
    logical :: unity

```

```

    type(string_t), dimension(:), allocatable :: prt_in
    type(string_t), dimension(:), allocatable :: prt_out
    integer :: n_in
    integer :: n_out
    integer :: n_tot
contains
    <Template matrix elements: template ME writer: TBP>
end type template_me_writer_t

```

The reported type is the same as for the `template_me_def_t` type.

```

<Template matrix elements: template ME writer: TBP>≡
    procedure, nopass :: type_name => template_me_writer_type_name
<Template matrix elements: procedures>+≡
    function template_me_writer_type_name () result (string)
        type(string_t) :: string
        string = "template"
    end function template_me_writer_type_name

```

Taking into account the prefix for template ME module names.

```

<Template matrix elements: template ME writer: TBP>+≡
    procedure, nopass :: get_module_name => template_me_writer_get_module_name
<Template matrix elements: procedures>+≡
    function template_me_writer_get_module_name (id) result (name)
        type(string_t) :: name
        type(string_t), intent(in) :: id
        name = "tpr_" // id
    end function template_me_writer_get_module_name

```

Output. This is called by `template_me_def_write`.

```

<Template matrix elements: template ME writer: TBP>+≡
    procedure :: write => template_me_writer_write
<Template matrix elements: procedures>+≡
    subroutine template_me_writer_write (object, unit)
        class(template_me_writer_t), intent(in) :: object
        integer, intent(in) :: unit
        integer :: i, j
        write (unit, "(5x,A,I0)") "# incoming part. = ", object%n_in
        write (unit, "(7x,A)", advance="no") &
            "    Initial state: "
        do i = 1, object%n_in - 1
            write (unit, "(1x,A)", advance="no") char (object%prt_in(i))
        end do
        write (unit, "(1x,A)") char (object%prt_in(object%n_in))
        write (unit, "(5x,A,I0)") "# outgoing part. = ", object%n_out
        write (unit, "(7x,A)", advance="no") &
            "    Final state:  "
        do j = 1, object%n_out - 1
            write (unit, "(1x,A)", advance="no") char (object%prt_out(i))
        end do
        write (unit, "(1x,A)") char (object%prt_out(object%n_out))
        write (unit, "(5x,A,I0)") "# part. (total) = ", object%n_tot
    end subroutine template_me_writer_write

```

```
end subroutine template_me_writer_write
```

Initialize with process data.

```
<Template matrix elements: template ME writer: TBP>+=
  procedure :: init => template_me_writer_init

<Template matrix elements: procedures>+=
  subroutine template_me_writer_init (writer, model, &
    prt_in, prt_out, unity)
    class(template_me_writer_t), intent(out) :: writer
    type(model_t), intent(in), target :: model
    type(string_t), dimension(:), intent(in) :: prt_in
    type(string_t), dimension(:), intent(in) :: prt_out
    logical, intent(in) :: unity
    writer%model => model
    writer%model_name = model%get_name ()
    writer%n_in = size (prt_in)
    writer%n_out = size (prt_out)
    writer%n_tot = size (prt_in) + size (prt_out)
    allocate (writer%prt_in (size (prt_in)), source = prt_in)
    allocate (writer%prt_out (size (prt_out)), source = prt_out)
    writer%unity = unity
  end subroutine template_me_writer_init
```

The makefile is the driver file for the test matrix elements.

```
<Template matrix elements: template ME writer: TBP>+=
  procedure :: write_makefile_code => template_me_write_makefile_code

<Template matrix elements: procedures>+=
  subroutine template_me_write_makefile_code (writer, unit, id, os_data, testflag)

31.1.3 Driver

<Template matrix elements: types>+≡

```

type, extends (prc_core_driver_t) :: template_me_driver_t
procedure(init_t), nopass, pointer :: &
init => null ()
procedure(update_alpha_s_t), nopass, pointer :: &
update_alpha_s => null ()
procedure(is_allowed_t), nopass, pointer :: &
is_allowed => null ()
procedure(new_event_t), nopass, pointer :: &
new_event => null ()
procedure(get_amplitude_t), nopass, pointer :: &
get_amplitude => null ()
contains
<Template matrix elements: template ME driver: TBP>
end type template_me_driver_t

```

The reported type is the same as for the `template_me_def_t` type.

```

<Template matrix elements: template ME driver: TBP>≡
    procedure, nopass :: type_name => template_me_driver_type_name
<Template matrix elements: procedures>+≡
    function template_me_driver_type_name () result (string)
        type(string_t) :: string
        string = "template"
    end function template_me_driver_type_name

```

31.1.4 High-level process definition

This procedure wraps the details filling a process-component definition entry as appropriate for an template matrix element.

NOTE: For calling the `import_component` method, we must explicitly address the `process_def_t` parent object. The natural way to call the method of the extended type triggers a bug in gfortran 4.6. The string array arguments `prt_in` and `prt_out` become corrupted and cause a segfault.

```

<Template matrix elements: public>+≡
    public :: template_me_make_process_component
<Template matrix elements: procedures>+≡
    subroutine template_me_make_process_component (entry, component_index, &
        model, model_name, prt_in, prt_out, unity)
        class(process_def_entry_t), intent(inout) :: entry
        integer, intent(in) :: component_index
        type(string_t), intent(in) :: model_name
        type(model_t), intent(in), target :: model
        type(string_t), dimension(:), intent(in) :: prt_in
        type(string_t), dimension(:), intent(in) :: prt_out
        logical, intent(in) :: unity
        class(prc_core_def_t), allocatable :: def
        allocate (template_me_def_t :: def)
        select type (def)
            type is (template_me_def_t)
                call def%init (model, prt_in, prt_out, unity)
            end select
        call entry%process_def_t%import_component (component_index, &
            n_out = size (prt_out), &
            prt_in = new_prt_spec (prt_in), &
            prt_out = new_prt_spec (prt_out), &
            method = var_str ("template"), &
            variant = def)
    end subroutine template_me_make_process_component

```

31.1.5 The `prc_template_me_t` wrapper

This is an instance of the generic `prc_core_t` object. It contains a pointer to the process definition (`template_me_def_t`), a data component (`process_constants_t`),

```

and the matrix-element driver (template_me_driver_t).
<Template matrix elements: public>+≡
    public :: prc_template_me_t
<Template matrix elements: types>+≡
    type, extends (prc_core_t) :: prc_template_me_t
        real(default), dimension(:), allocatable :: par
    contains
        <Template matrix elements: prc template ME: TBP>
    end type prc_template_me_t

```

The workspace associated to a `prc_template_me_t` object contains a single flag. The flag is used to suppress re-evaluating the matrix element for each quantum-number combination, after the first amplitude belonging to a given kinematics has been computed.

We can also store the value of a running coupling once it has been calculated for an event. The default value is negative, which indicates an undefined value in this context.

```

<Template matrix elements: types>+≡
    type, extends (workspace_t) :: template_me_state_t
        logical :: new_kinematics = .true.
        real(default) :: alpha_qcd = -1
    contains
        procedure :: write => template_me_state_write
        procedure :: reset_new_kinematics => template_me_state_reset_new_kinematics
    end type template_me_state_t

<Template matrix elements: procedures>+≡
    subroutine template_me_state_write (object, unit)
        class(template_me_state_t), intent(in) :: object
        integer, intent(in), optional :: unit
        integer :: u
        u = given_output_unit (unit)
        write (u, "(3x,A,L1)") "Template ME state: new kinematics = ", &
            object%new_kinematics
    end subroutine template_me_state_write

```

```

<Template matrix elements: procedures>+≡
    subroutine template_me_state_reset_new_kinematics (object)
        class(template_me_state_t), intent(inout) :: object
    end subroutine template_me_state_reset_new_kinematics

```

Allocate the workspace with the above specific type.

```

<Template matrix elements: prc template ME: TBP>≡
    procedure :: allocate_workspace => prc_template_me_allocate_workspace

<Template matrix elements: procedures>+≡
    subroutine prc_template_me_allocate_workspace (object, tmp)
        class(prc_template_me_t), intent(in) :: object
        class(workspace_t), intent(inout), allocatable :: tmp
        allocate (template_me_state_t :: tmp)
    end subroutine prc_template_me_allocate_workspace

```

The following procedures are inherited from the base type as deferred, thus must be implemented. The corresponding unit tests are skipped here; the procedures are tested when called from the `processes` module.

Output: print just the ID of the associated matrix element. Then display any stored parameters.

```

<Template matrix elements: prc_template ME: TBP>+≡
  procedure :: write => prc_template_me_write

<Template matrix elements: procedures>+≡
  subroutine prc_template_me_write (object, unit)
    class(prc_template_me_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(3x,A)", advance="no") "Template process core:"
    if (object%data_known) then
      write (u, "(1x,A)") char (object%data%id)
    else
      write (u, "(1x,A)") "[undefined]"
    end if
    if (allocated (object%par)) then
      write (u, "(3x,A)") "Parameter array:"
      do i = 1, size (object%par)
        write (u, "(5x,I0,1x,ES17.10)") i, object%par(i)
      end do
    end if
  end subroutine prc_template_me_write

```

Temporarily store the parameter array inside the `prc_template_me` object, so we can use it later during the actual initialization.

```

<Template matrix elements: prc_template ME: TBP>+≡
  procedure :: set_parameters => prc_template_me_set_parameters

<Template matrix elements: procedures>+≡
  subroutine prc_template_me_set_parameters (prc_template_me, model)
    class(prc_template_me_t), intent(inout) :: prc_template_me
    class(model_data_t), intent(in), target, optional :: model
    if (present (model)) then
      if (.not. allocated (prc_template_me%par)) &
        allocate (prc_template_me%par (model%get_n_real ()))
      call model%real_parameters_to_c_array (prc_template_me%par)
    end if
  end subroutine prc_template_me_set_parameters

```

To fully initialize the process core, we perform base initialization, then initialize the external matrix element code.

This procedure overrides the `init` method of the base type, which we nevertheless can access via its binding `base_init`. When done, we have an allocated driver. The driver will call the `init` procedure for the external matrix element, and thus transfer the parameter set to where it finally belongs.

```

<Template matrix elements: prc_template ME: TBP>+≡
  procedure :: init => prc_template_me_init

```

```

<Template matrix elements: procedures>+≡
  subroutine prc_template_me_init (object, def, lib, id, i_component)
    class(prc_template_me_t), intent(inout) :: object
    class(prc_core_def_t), intent(in), target :: def
    type(process_library_t), intent(in), target :: lib
    type(string_t), intent(in) :: id
    integer, intent(in) :: i_component
    call object%base_init (def, lib, id, i_component)
    call object%activate_parameters ()
  end subroutine prc_template_me_init

```

Activate the stored parameters by transferring them to the external matrix element.

```

<Template matrix elements: prc template ME: TBP>+≡
  procedure :: activate_parameters => prc_template_me_activate_parameters

```

```

<Template matrix elements: procedures>+≡
  subroutine prc_template_me_activate_parameters (object)
    class (prc_template_me_t), intent(inout) :: object
    if (allocated (object%driver)) then
      if (allocated (object%par)) then
        select type (driver => object%driver)

    logical(c_bool) :: cflag
    select type (driver => object%driver)
    type is (template_me_driver_t)
      call driver%is_allowed (f, h, c, cflag)
      flag = cflag
    end select
  end function prc_template_me_is_allowed

```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

We reset the `new_kinematics` flag, so that the next call to `compute_amplitude` will evaluate the matrix element.

```

<Template matrix elements: prc template ME: TBP>+=
  procedure :: compute_hard_kinematics => &
    prc_template_me_compute_hard_kinematics

<Template matrix elements: procedures>+=
  subroutine prc_template_me_compute_hard_kinematics &
    (object, p_seed, i_term, int_hard, tmp)
    class(prc_template_me_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(in) :: p_seed
    integer, intent(in) :: i_term
    type(interaction_t), intent(inout) :: int_hard
    class(workspace_t), intent(inout), allocatable :: tmp
    call interaction_set_momenta (int_hard, p_seed)
    if (allocated (tmp)) then
      select type (tmp)
      type is (template_me_state_t); tmp%new_kinematics = .true.
      end select
    end if
  end subroutine prc_template_me_compute_hard_kinematics

```

This procedure is not called for `prc_template_me_t`, just a placeholder.

```

<Template matrix elements: prc template ME: TBP>+=
  procedure :: compute_eff_kinematics => &
    prc_template_me_compute_eff_kinematics

<Template matrix elements: procedures>+=
  subroutine prc_template_me_compute_eff_kinematics &
    (object, i_term, int_hard, int_eff, tmp)

```

```

class(prc_template_me_t), intent(in) :: object
integer, intent(in) :: i_term

type(interaction_t), intent(inout) :: int_eff
class(workspace_t), intent(inout), allocatable :: tmp
end subroutine prc_template_me_compute_eff_kinematics

```

Recover the momenta within the hard interaction. For tree-level processes, this is a trivial copy of the incoming seed and outgoing effective momenta. The effective interaction is a pointer to the hard interaction, so the latter is ignored.

<Template matrix elements: prc template ME: TBP>+≡

```

procedure :: recover_kinematics => prc_template_me_recover_kinematics

```

<Template matrix elements: tests>≡

```

subroutine prc_template_me_recover_kinematics &
  (object, p_seed, int_hard, int_eff, tmp)
  class(prc_template_me_t), intent(in) :: object
  type(vector4_t), dimension(:), intent(inout) :: p_seed
  type(interaction_t), intent(inout) :: int_hard
  type(interaction_t), intent(inout) :: int_eff
  class(workspace_t), intent(inout), allocatable :: tmp
  integer :: n_in
  n_in = interaction_get_n_in (int_eff)
  call interaction_set_momenta (int_eff, p_seed(1:n_in), outgoing = .false.)
  p_seed(n_in+1:) = interaction_get_momenta (int_eff, outgoing = .true.)
end subroutine prc_template_me_recover_kinematics

```

Compute the amplitude. For the tree-level process, we can ignore the scale settings. The term index j is also irrelevant.

We first call `new_event` for the given momenta (which we must unpack), then retrieve the amplitude value for the given quantum numbers.

If the `tmp` status flag is present, we can make sure that we call `new_event` only once for a given kinematics. After the first call, we unset the `new_kinematics` flag.

<Template matrix elements: prc template ME: TBP>+≡

```

procedure :: compute_amplitude => prc_template_me_compute_amplitude

```

<Template matrix elements: procedures>+≡

```

  amp = camp
else
  amp = 0
end if
end select
end function prc_template_me_compute_amplitude

```

We do not overwrite the `prc_core_t` routine for α_s .

31.1.6 Test

This is the master for calling self-test procedures. There is a separate test for testing O'MEGA diagram generation as this depends on a working analysis setup.

```

<Template matrix elements: public>+≡
  public :: prc_template_me_test

<Template matrix elements: tests>+≡
  subroutine prc_template_me_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <Template matrix elements: execute tests>
  end subroutine prc_template_me_test

```

Generate, compile and load a simple process matrix element

The process is $e^+e^- \rightarrow \mu^+\mu^-$ for vanishing masses and $e = 0.3$. We initialize the process, build the library, and compute a particular matrix element for momenta of unit energy and right-angle scattering. The matrix element, as it happens, is equal to e^2 . (Note that are no conversion factors applied, so this result is exact.)

For GNU make, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

```

<Template matrix elements: execute tests>≡

```

```

call test (prc_template_me_1, "prc_template_me_1", &
          "build and load simple template process", &
          u, results)

31.2 O'MEGA Interface

The standard method for process computation with WHIZARD is the O'MEGA matrix element generator.

This section implements the interface to the code generator (via the makefile) and the driver for the features provided by the O'MEGA matrix element.

There are actually two different methods steered by this interface, the traditional one which delivers compiled Fortran code, while the O'MEGA virtual machine (OVM) produces bytecode with look-up tables.

```

The reported type is the same as for the `omega_def_t` type.

```

<Omega interface: omega driver: TBP>≡
  procedure, nopass :: type_name => omega_driver_type_name

<Omega interface: procedures>+≡
  function omega_driver_type_name () result (string)
    type(string_t) :: string
    string = "omega"
  end function omega_driver_type_name

```

31.2.4 High-level process definition

This procedure wraps the details filling a process-component definition entry as appropriate for an O'MEGA matrix element.

NOTE: For calling the `import_component` method, we must explicitly address the `process_def_t` parent object. The natural way to call the method of the extended type triggers a bug in gfortran 4.6. The string array arguments `prt_in` and `prt_out` become corrupted and cause a segfault.

```

<Omega interface: public>+≡
  public :: omega_make_process_component

<Omega interface: procedures>+≡
  subroutine omega_make_process_component (entry, component_index, &
    model_name, prt_in, prt_out, restrictions, openmp_support, &
    report_progress, extra_options, diags, diags_color)
    class(process_def_entry_t), intent(inout) :: entry
    integer, intent(in) :: component_index
    type(string_t), intent(in) :: model_name
    type(string_t), dimension(:), intent(in) :: prt_in
    type(string_t), dimension(:), intent(in) :: prt_out

```

```

type(string_t), intent(in), optional :: restrictions
logical, intent(in), optional :: openmp_support
logical, intent(in), optional :: report_progress
logical, intent(in), optional :: diags, diags_color
type(string_t), intent(in), optional :: extra_options
class(prc_core_def_t), allocatable :: def
allocate (omega_omega_def_t :: def)
select type (def)
type is (omega_omega_def_t)
    call def%init (model_name, prt_in, prt_out, &
        restrictions, openmp_support, report_progress, &
        extra_options, diags, diags_color)
end select
call entry%process_def_t%import_component (component_index, &
    n_out = size (prt_out), &
    prt_in = new_prt_spec (prt_in), &
    prt_out = new_prt_spec (prt_out), &
    method = var_str ("omega"), &
    variant = def)
end subroutine omega_make_process_component

```

31.2.5 The prc_omega_t wrapper

This is an instance of the generic `prc_core_t` object. It contains a pointer to the process definition (`omega_def_t`), a data component (`process_constants_t`), and the matrix-element driver (`omega_driver_t`).

```

<Omega interface: public>+≡
    public :: prc_omega_t

<Omega interface: types>+≡
    type, extends (prc_core_t) :: prc_omega_t
        real(default), dimension(:), allocatable :: par
        type(helicity_selection_t) :: helicity_selection
        type(qcd_t) :: qcd
    contains
        <Omega interface: prc omega: TBP>
    end type prc_omega_t

```

The workspace associated to a `prc_omega_t` object contains a single flag. The flag is used to suppress re-evaluating the matrix element for each quantum-number combination, after the first amplitude belonging to a given kinematics has been computed.

We can also store the value of a running coupling once it has been calculated for an event. The default value is negative, which indicates an undefined value in this context.

```

<Omega interface: types>+≡
    type, extends (workspace_t) :: omega_state_t
        logical :: new_kinematics = .true.
        real(default) :: alpha_qcd = -1
    contains
        procedure :: write => omega_state_write

```

```

    procedure :: reset_new_kinematics => omega_state_reset_new_kinematics
end type omega_state_t

```

```

<Omega interface: procedures>+≡
subroutine omega_state_write (object, unit)
  class(omega_state_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u
  u = given_output_unit (unit)
  write (u, "(3x,A,L1)") "0'Mega state: new kinematics = ", &
    object%new_kinematics
end subroutine omega_state_write

```

```

<Omega interface: procedures>+≡
subroutine omega_state_reset_new_kinematics (object)
  class(omega_state_t), intent(inout) :: object
  object%new_kinematics = .true.
end subroutine omega_state_reset_new_kinematics

```

Allocate the workspace with the above specific type.

```

<Omega interface: prc omega: TBP>≡
  procedure :: allocate_workspace => prc_omega_allocate_workspace

<Omega interface: procedures>+≡
subroutine prc_omega_allocate_workspace (object, tmp)
  class(prc_omega_t), intent(in) :: object
  class(workspace_t), intent(inout), allocatable :: tmp
  allocate (omega_state_t :: tmp)
end subroutine prc_omega_allocate_workspace

```

The following procedures are inherited from the base type as deferred, thus must be implemented. The corresponding unit tests are skipped here; the procedures are tested when called from the `processes` module.

Output: print just the ID of the associated matrix element. Then display any stored parameters and the helicity selection data. (The latter are printed only if active.)

```

<Omega interface: prc omega: TBP>+≡
  procedure :: write => prc_omega_write

<Omega interface: procedures>+≡
subroutine prc_omega_write (object, unit)
  class(prc_omega_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u, i
  u = given_output_unit (unit)
  write (u, "(3x,A)", advance="no") "0'Mega process core:"
  if (object%data_known) then
    write (u, "(1x,A)") char (object%data%id)
  else
    write (u, "(1x,A)") "[undefined]"
  end if
  if (allocated (object%par)) then

```

```

        write (u, "(3x,A)") "Parameter array:"
        do i = 1, size (object%par)
            write (u, "(5x,I0,1x,ES17.10)") i, object%par(i)
        end do
    end if
    call object%helicity_selection%write (u)
    call object%qcd%write (u)
end subroutine prc_omega_write

```

Temporarily store the parameter array inside the `prc_omega` object, so we can use it later during the actual initialization. Also store threshold and cutoff for helicity selection.

```

<Omega interface: prc omega: TBP>+≡
    procedure :: set_parameters => prc_omega_set_parameters

<Omega interface: procedures>+≡
    subroutine prc_omega_set_parameters (prc_omega, model, &

            prc_omega%use_color_factors = use_color_factors
        end if
    end subroutine prc_omega_set_parameters

```

To fully initialize the process core, we perform base initialization, then initialize the external matrix element code.

This procedure overrides the `init` method of the base type, which we nevertheless can access via its binding `base_init`. When done, we have an allocated driver. The driver will call the `init` procedure for the external matrix element, and thus transfer the parameter set to where it finally belongs.

If requested, we initialize the helicity selection counter.

```

<Omega interface: prc omega: TBP>+≡
    procedure :: init => prc_omega_init

<Omega interface: procedures>+≡
    subroutine prc_omega_init (object, def, lib, id, i_component)
        class(prc_omega_t), intent(inout) :: object
        class(prc_core_def_t), intent(in), target :: def

```

```

type(process_library_t), intent(in), target :: lib
type(string_t), intent(in) :: id
integer, intent(in) :: i_component
call object%base_init (def, lib, id, i_component)
call object%activate_parameters ()
end subroutine prc_omega_init

```

Activate the stored parameters by transferring them to the external matrix element. Also reset the helicity selection, if requested.

```

<Omega interface: prc omega: TBP>+≡
  procedure :: activate_parameters => prc_omega_activate_parameters

<Omega interface: procedures>+≡
  subroutine prc_omega_activate_parameters (object)
    class (prc_omega_t), intent(inout) :: object
    if (allocated (object%driver)) then
      if (allocated (object%par)) then

        end if
      end if
    end select
  end subroutine prc_omega_reset_helicity_selection

```

Compute the amplitude. For the tree-level process, we can ignore the scale settings. The term index `j` is also irrelevant.

We first call `new_event` for the given momenta (which we must unpack), then retrieve the amplitude value for the given quantum numbers.

If the `tmp` status flag is present, we can make sure that we call `new_event` only once for a given kinematics. After the first call, we unset the `new_kinematics`

flag.

The `is_allowed` query is not redundant, since the status may change during the run if helicities are switched off.

```

(Omega interface: prc omega: TBP) +=
  procedure :: compute_amplitude => prc_omega_compute_amplitude

(Omega interface: procedures) +=
  function prc_omega_compute_amplitude &

    subroutine prc_omega_diags_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
        <Omega interface: execute diags tests>
    end subroutine prc_omega_diags_test

```

Generate, compile and load a simple process matrix element

The process is $e^+e^- \rightarrow \mu^+\mu^-$ for vanishing masses and $e = 0.3$. We initialize the process, build the library, and compute a particular matrix element for momenta of unit energy and right-angle scattering. The matrix element, as it happens, is equal to e^2 . (Note that are no conversion factors applied, so this result is exact.)

For GNU make, makeflags is set to -j1. This eliminates a potential clash with a -j<n> flag if this test is called from a parallel make.

```

(Omega interface: execute tests)≡
    call test (prc_omega_1, "prc_omega_1", &

Check prc_omega_t wrapper and options

The process is $e^-e^+ \rightarrow e^-e^+$ for vanishing masses and $e = 0.3$. We build the library using the high-level procedure `omega_make_process_component` and the “black box” `prc_omega_t` object. Two variants with different settings for restrictions and OpenMP.

For GNU `make`, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

```

Chapter 32

Event I/O

In this chapter we provide a generic handler for event I/O and the various implementations: raw, HepMC, Les Houches, etc.

32.1 Event Sample Data

We define a simple and transparent container for (meta)data that are associated with an event sample.

```
<eio_data.f90>≡  
  <File header>  
  
  module eio_data  
  
    use kinds  
    use io_units  
    <Use strings>  
    use unit_tests  
    use diagnostics  
  
    use events  
  
    <EIO data: public>  
  
    <EIO data: types>  
  
    contains  
  
    <EIO data: procedures>  
  
    <EIO data: tests>  
  
  end module eio_data
```

32.1.1 Event Sample Data

These are data that apply to an event sample as a whole. They are given in an easily portable form (no fancy structure) and are used for initializing event

formats.

There are two MD5 sums here. `md5sum_proc` depends only on the definition of the contributing processes. A sample with matching checksum can be rescanned with modified model parameters, beam structure etc, to recalculate observables. `md5sum_config` includes all relevant data. Rescanning a sample with matching checksum will produce identical observables. (A third checksum might be added which depends on the event sample itself. This is not needed, so far.)

If alternate weights are part of the event sample (`n_alt` nonzero), there is a configuration MD5 sum for each of them.

```

(EIO data: public)≡
    public :: event_sample_data_t

(EIO data: types)≡
    type :: event_sample_data_t
        character(32) :: md5sum_proc = ""

```

32.2 Abstract I/O Handler

This module defines an abstract object for event I/O and the associated methods.

There are `output` and `input` methods which write or read a single event from/to the I/O stream, respectively. The I/O stream itself may be a file, a common block, or an externally linked structure, depending on the concrete implementation.

A `write` method prints the current content of the implementation-dependent event record in human-readable form.

The `init_in/init_out` and `final` prepare and finalize the I/O stream, respectively. There is also a `switch_inout` method which turns an input stream into an output stream where events can be appended.

Optionally, output files can be split in chunks of well-defined size. The `split_out` method takes care of this.

```

<eio_base.f90>≡
  <File header>

  module eio_base

    use kinds
    use io_units
  <Use strings>
    use unit_tests
    use diagnostics

    use lorentz
    use model_data
    use particles
    use beams
    use processes
    use events
    use eio_data

  <Standard module head>

  <EIO base: public>

  <EIO base: types>

  <EIO base: interfaces>

  <EIO base: test types>

  contains

  <EIO base: procedures>

  <EIO base: tests>

  end module eio_base

```

32.2.1 Process pointer

For handling multiple processes, we need an array of process pointers. This requires a wrapper:

```

<EIO base: public>≡
  public :: process_ptr_t

<EIO base: types>≡
  type :: process_ptr_t
    type(process_t), pointer :: ptr => null ()
  end type process_ptr_t

```

32.2.2 Type

We can assume that most implementations will need the file extension as a fixed string and, if they support file splitting, the current file index.

The fallback model is useful for implementations that are able to read unknown files which may contain hadrons etc., not in the current hard-interaction model.

```
<EIO base: public>+≡
    public :: eio_t

<EIO base: types>+≡
    type, abstract :: eio_t
        type(string_t) :: sample
        type(string_t) :: extension
        type(string_t) :: filename
        logical :: split = .false.
        integer :: split_n_evt = 0
        integer :: split_index = 0
        class(model_data_t), pointer :: fallback_model => null ()
    contains
        <EIO base: eio: TBP>
    end type eio_t
```

Write to screen. If possible, this should display the contents of the current event, i.e., the last one that was written or read.

```
<EIO base: eio: TBP>≡
    procedure (eio_write), deferred :: write

<EIO base: interfaces>≡
    abstract interface
        subroutine eio_write (object, unit)
            import
            class(eio_t), intent(in) :: object
            integer, intent(in), optional :: unit
        end subroutine eio_write
    end interface
```

Finalize. This should write/read footer data and close input/output channels.

```
<EIO base: eio: TBP>+≡
    procedure (eio_final), deferred :: final

<EIO base: interfaces>+≡
    abstract interface
        subroutine eio_final (object)
            import
            class(eio_t), intent(inout) :: object
        end subroutine eio_final
    end interface
```

Determine splitting parameters from the event sample data.

```
<EIO base: eio: TBP>+≡
    procedure :: set_splitting => eio_set_splitting
```

```

(EIO base: procedures)≡
subroutine eio_set_splitting (eio, data)
  class(eio_t), intent(inout) :: eio
  type(event_sample_data_t), intent(in) :: data
  eio%split = data%split_n_evt > 0
  if (eio%split) then
    eio%split_n_evt = data%split_n_evt
    eio%split_index = data%split_index
  end if
end subroutine eio_set_splitting

```

Generate a filename, taking a possible split index into account.

```

(EIO base: eio: TBP)+≡
  procedure :: set_filename => eio_set_filename

(EIO base: procedures)+≡
subroutine eio_set_filename (eio)
  class(eio_t), intent(inout) :: eio
  character(32) :: buffer
  if (eio%split) then
    write (buffer, "(I0,'.')") eio%split_index
    eio%filename = eio%sample // "." // trim (buffer) // eio%extension
  else
    eio%filename = eio%sample // "." // eio%extension
  end if
end subroutine eio_set_filename

```

Set the fallback model.

```

(EIO base: eio: TBP)+≡
  procedure :: set_fallback_model => eio_set_fallback_model

(EIO base: procedures)+≡
subroutine eio_set_fallback_model (eio, model)
  class(eio_t), intent(inout) :: eio
  class(model_data_t), intent(in), target :: model
  eio%fallback_model => model
end subroutine eio_set_fallback_model

```

Initialize for output. We provide process pointers. This should open an event file if appropriate and write header data. Some methods may require event sample data.

```

(EIO base: eio: TBP)+≡
  procedure (eio_init_out), deferred :: init_out

(EIO base: interfaces)+≡
abstract interface
  subroutine eio_init_out &
    (eio, sample, process_ptr, data, success, extension)
  import
  class(eio_t), intent(inout) :: eio
  type(string_t), intent(in) :: sample
  type(string_t), intent(in), optional :: extension
  type(process_ptr_t), dimension(:), intent(in) :: process_ptr

```

```

        type(event_sample_data_t), intent(in), optional :: data
        logical, intent(out), optional :: success
    end subroutine eio_init_out
end interface

```

Initialize for input. We provide process names. This should open an event file if appropriate and read header data. The `md5sum` can be used to check the integrity of the configuration, it provides a checksum to compare with. In case the extension has changed the extension is also given as an argument.

The `data` argument is `intent(inout)`: we may read part of it and keep other parts and/or check them against the data in the file.

```

(EIO base: eio: TBP)+≡
    procedure (eio_init_in), deferred :: init_in

(EIO base: interfaces)+≡
    abstract interface
        subroutine eio_init_in &
            (eio, sample, process_ptr, data, success, extension)
        import
        class(eio_t), intent(inout) :: eio
        type(string_t), intent(in) :: sample
        type(string_t), intent(in), optional :: extension
        type(process_ptr_t), dimension(:), intent(in) :: process_ptr
        type(event_sample_data_t), intent(inout), optional :: data
        logical, intent(out), optional :: success
    end subroutine eio_init_in
end interface

```

Re-initialize for output. This should change the status of any event file from input to output and position it for appending new events.

```

(EIO base: eio: TBP)+≡
    procedure (eio_switch_inout), deferred :: switch_inout

(EIO base: interfaces)+≡
    abstract interface
        subroutine eio_switch_inout (eio, success)
        import
        class(eio_t), intent(inout) :: eio
        logical, intent(out), optional :: success
    end subroutine eio_switch_inout
end interface

```

This is similar: split the output, i.e., close the current file and open a new one. The default implementation does nothing. For the feature to work, an implementation must override this.

```

(EIO base: eio: TBP)+≡
    procedure :: split_out => eio_split_out

(EIO base: procedures)+≡
    subroutine eio_split_out (eio)
        class(eio_t), intent(inout) :: eio
    end subroutine eio_split_out

```

Output an event. All data can be taken from the `event` record. The index `i_prc` identifies the process among the processes that are contained in the current sample. The `reading` flag, if present, indicates that the event was read from file, not generated.

```

(EIO base: eio: TBP)+≡
  procedure (eio_output), deferred :: output

(EIO base: interfaces)+≡
  abstract interface
    subroutine eio_output (eio, event, i_prc, reading)
      import
      class(eio_t), intent(inout) :: eio
      type(event_t), intent(in), target :: event
      integer, intent(in) :: i_prc
      logical, intent(in), optional :: reading
    end subroutine eio_output
  end interface

```

Input an event. This should fill all event data that cannot be inferred from the associated process.

The input is broken down into two parts. First we read the `i_prc` index. So we know which process to expect in the subsequent event. If we have reached end of file, we also will know. Then, we read the event itself.

The parameter `iostat` is supposed to be set as the Fortran standard requires, negative for EOF and positive for error.

```

(EIO base: eio: TBP)+≡
  procedure (eio_input_i_prc), deferred :: input_i_prc
  procedure (eio_input_event), deferred :: input_event

(EIO base: interfaces)+≡
  abstract interface
    subroutine eio_input_i_prc (eio, i_prc, iostat)
      import
      class(eio_t), intent(inout) :: eio
      integer, intent(out) :: i_prc
      integer, intent(out) :: iostat
    end subroutine eio_input_i_prc
  end interface

  abstract interface
    subroutine eio_input_event (eio, event, iostat)
      import
      class(eio_t), intent(inout) :: eio
      type(event_t), intent(inout), target :: event
      integer, intent(out) :: iostat
    end subroutine eio_input_event
  end interface

```

32.2.3 Unit tests

```

(EIO base: public)+≡
  public :: eio_base_test

```

```

<EIO base: tests>≡
  subroutine eio_base_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <EIO base: execute tests>
  end subroutine eio_base_test

```

Test type for event I/O

The contents simulate the contents of an external file. We have the `sample` string as the file name, `sqrts` and the array of `process_ids` as metadata, and the array of momenta `event_p` as the list of events. The second index is the event index. The `event_i` component is the pointer to the current event, `event_n` is the total number of stored events.

```

<EIO base: test types>≡
  type, extends (eio_t) :: eio_test_t
    real(default) :: sqrts
    type(string_t) :: process_id
    integer :: event_n = 0
    integer :: event_i = 0
    integer :: i_prc = 0
    type(vector4_t), dimension(:,,:), allocatable :: event_p
  contains
    <EIO base: eio test: TBP>
  end type eio_test_t

```

Write to screen. Pretend that this is an actual event format.

```

<EIO base: eio test: TBP>≡
  procedure :: write => eio_test_write

<EIO base: procedures>+≡
  subroutine eio_test_write (object, unit)
    class(eio_test_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(1x,A)") "Test event stream"
    write (u, "(3x,A,A,A)") "Process ID = '", char (object%process_id), "'"
    write (u, "(3x,A,ES19.12)") "sqrts      = ", object%sqrts
    if (object%event_i /= 0) then
      write (u, "(1x,A,I0,A)") "Event #", object%event_i, ":"
      do i = 1, size (object%event_p, 1)
        call vector4_write (object%event_p(i, object%event_i), u)
      end do
    end if
  end subroutine eio_test_write

```

Finalizer. For the test case, we just reset the event count, but keep the stored “events”. For the real implementations, the events would be stored on an external medium, so we would delete the object contents.

```

<EIO base: eio test: TBP>+≡
  procedure :: final => eio_test_final

```

```

<EIO base: procedures>+=
  subroutine eio_test_final (object)
    class(eio_test_t), intent(inout) :: object
    object%event_i = 0
  end subroutine eio_test_final

```

Initialization: We store the process IDs and the energy from the beam-data object. We also allocate the momenta (i.e., the simulated event record) for a fixed maximum size of 10 events, 2 momenta each. There is only a single process.

```

<EIO base: eio test: TBP>+=
  procedure :: init_out => eio_test_init_out

<EIO base: procedures>+=
  subroutine eio_test_init_out &
    (eio, sample, process_ptr, data, success, extension)
    class(eio_test_t), intent(inout) :: eio
    type(string_t), intent(in) :: sample

Output an event. Write first the event indices, then weight and squared matrix element, then the particle set.

We always write the particle set of the hard process. (Note: this should be reconsidered.) We do make a physical copy.

On output, we write the **prc** values for weight and sqme, since these are the values just computed. On input, we store the values as **ref** values. The caller can then decide whether to recompute values and thus obtain distinct **prc** values, or just accept them.

```

32.5 HEP Common Blocks

Long ago, to transfer data between programs one had to set up a common block and link both programs as libraries to the main executable. The HEP community standardizes several of those common blocks.

The modern way of data exchange uses data files with standard formats. However, the LHEF standard data format derives from a common block (actually, two).

WHIZARD used to support those common blocks, and LHEF was implemented via writing/reading blocks. We still keep this convention, but intend to eliminate common blocks (or any other static storage) from the workflow in the future. This will gain flexibility towards concurrent running of program images.

We encapsulate everything here in a module. The module holds the variables which are part of the common block.

Note: This code is taken essentially unchanged from WHIZARD 2.1 and does not (yet) provide unit tests.

```

<hep_common.f90>≡
  <File header>

```

```

module hep_common

    use kinds
    use io_units
    <Use strings>
    use diagnostics
    use physics_defs, only: HADRON_REMNANT
    use physics_defs, only: HADRON_REMNANT_SINGLET
    use physics_defs, only: HADRON_REMNANT_TRIPLET
    use physics_defs, only: HADRON_REMNANT_OCTET
    use lorentz
    use flavors
    use colors
    use polarizations
    use model_data
    use particles
    use subevents
    use processes

    <Standard module head>

    <HEP common: public>

    <HEP common: interfaces>

    <HEP common: parameters>

    <HEP common: variables>

    <HEP common: common blocks>

    contains

    <HEP common: procedures>

end module hep_common

```

32.5.1 Event characteristics

The maximal number of particles in an event record.

<HEP common: parameters>≡
integer, parameter :: MAXNUP = 500

The number of particles in this event.

<HEP common: variables>≡
integer :: NUP

The process ID for this event.

<HEP common: variables>+≡
integer :: IDPRUP

The weight of this event (± 1 for unweighted events).

<HEP common: variables>+≡
double precision :: XWGTUP

The factorization scale that is used for PDF calculation (-1 if undefined).

```
<HEP common: variables>+≡  
double precision :: SCALUP
```

The QED and QCD couplings α used for this event (-1 if undefined).

```
<HEP common: variables>+≡  
double precision :: AQEDUP  
double precision :: AQCDUP
```

32.5.2 Particle characteristics

The PDG code:

```
<HEP common: variables>+≡  
integer, dimension(MAXNUP) :: IDUP
```

The status code. Incoming: -1 , outgoing: $+1$. Intermediate t-channel propagator: -2 (currently not used by WHIZARD). Intermediate resonance whose mass should be preserved: 2 . Intermediate resonance for documentation: 3 (currently not used). Beam particles: -9 .

```
<HEP common: variables>+≡  
integer, dimension(MAXNUP) :: ISTUP
```

Index of first and last mother.

```
<HEP common: variables>+≡  
integer, dimension(2,MAXNUP) :: MOTHUP
```

Color line index of the color and anticolor entry for the particle. The standard recommends using large numbers; we start from $\text{MAXNUP}+1$.

```
<HEP common: variables>+≡  
integer, dimension(2,MAXNUP) :: ICOLUP
```

Momentum, energy, and invariant mass: (p_x, p_y, p_z, E, M) . For space-like particles, M is the negative square root of the absolute value of the invariant mass.

```
<HEP common: variables>+≡  
double precision, dimension(5,MAXNUP) :: PUP
```

Invariant lifetime (distance) from production to decay in mm.

```
<HEP common: variables>+≡  
double precision, dimension(MAXNUP) :: VTIMUP
```

Cosine of the angle between the spin-vector and a particle and the 3-momentum of its mother, given in the lab frame. If undefined/unpolarized: 9 .

```
<HEP common: variables>+≡  
double precision, dimension(MAXNUP) :: SPINUP
```

32.5.3 The HEPRUP common block

This common block is filled once per run.

Run characteristics

The maximal number of different processes.

```
<HEP common: parameters>+≡  
integer, parameter :: MAXPUP = 100
```

The beam PDG codes.

```
<HEP common: variables>+≡  
integer, dimension(2) :: IDBMUP
```

The beam energies in GeV.

```
<HEP common: variables>+≡  
double precision, dimension(2) :: EBMUP
```

The PDF group and set for the two beams. (Undefined: use -1; LHAPDF: use group = 0).

```
<HEP common: variables>+≡  
integer, dimension(2) :: PDFGUP  
integer, dimension(2) :: PDFSUP
```

The (re)weighting model. 1: events are weighted, the shower generator (SHG) selects processes according to the maximum weight (in pb) and unweights events. 2: events are weighted, the SHG selects processes according to their cross section (in pb) and unweights events. 3: events are unweighted and simply run through the SHG. 4: events are weighted, and the SHG keeps the weight. Negative numbers: negative weights are allowed (and are reweighted to ± 1 by the SHG, if allowed).

WHIZARD only supports modes 3 and 4, as the SHG is not given control over process selection. This is consistent with writing events to file, for offline showering.

```
<HEP common: variables>+≡  
integer :: IDWTUP
```

The number of different processes.

```
<HEP common: variables>+≡  
integer :: NPRUP
```

Process characteristics

Cross section and error in pb. (Cross section is needed only for IDWTUP = 2, so here both values are given for informational purposes only.)

```
<HEP common: variables>+≡  
double precision, dimension(MAXPUP) :: XSECUP  
double precision, dimension(MAXPUP) :: XERRUP
```

Maximum weight, i.e., the maximum value that XWGTUP can take. Also unused for the supported weighting models. It is ± 1 for unweighted events.

```
<HEP common: variables>+≡  
double precision, dimension(MAXPUP) :: XMAXUP
```

Internal ID of the selected process, matches IDPRUP below.

```
<HEP common: variables>+≡  
integer, dimension(MAXPUP) :: LPRUP
```

The common block

```
<HEP common: common blocks>≡  
common /HEPRUP/ &  
IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP, &  
XSECUP, XERRUP, XMAXUP, LPRUP  
save /HEPRUP/
```

Fill the run characteristics of the common block. The initialization sets the beam properties, number of processes, and weighting model.

```

<HEP common: public>≡
  public :: heprup_init

<HEP common: procedures>≡
  subroutine heprup_init &
    (beam_pdg, beam_energy, n_processes, unweighted, negative_weights)
    integer, dimension(2), intent(in) :: beam_pdg
    real(default), dimension(2), intent(in) :: beam_energy
    integer, intent(in) :: n_processes
    logical, intent(in) :: unweighted
    logical, intent(in) :: negative_weights
    IDBMUP = beam_pdg
    EBMUP = beam_energy
    PDFGUP = -1
    PDFSUP = -1
    if (unweighted) then
      IDWTUP = 3
    else
      IDWTUP = 4
    end if
    if (negative_weights) IDWTUP = - IDWTUP
    NPRUP = n_processes
  end subroutine heprup_init

```

Extract parameters from the common block. We leave it to the caller to specify which parameters it actually needs.

PDFGUP and PDFSUP are not extracted. IDWTUP=1,2 are not supported by WHIZARD, but correspond to weighted events.

```

<HEP common: public>+≡
  public :: heprup_get_run_parameters

<HEP common: procedures>+≡
  subroutine heprup_get_run_parameters &
    (beam_pdg, beam_energy, n_processes, unweighted, negative_weights)
    integer, dimension(2), intent(out), optional :: beam_pdg
    real(default), dimension(2), intent(out), optional :: beam_energy
    integer, intent(out), optional :: n_processes
    logical, intent(out), optional :: unweighted
    logical, intent(out), optional :: negative_weights
    if (present (beam_pdg)) beam_pdg = IDBMUP
    if (present (beam_energy)) beam_energy = EBMUP
    if (present (n_processes)) n_processes = NPRUP

        "Subprocess ID"
end do
end subroutine heprup_write_verbose

```

32.5.5 Run parameter output (other formats)

This routine writes the initialization block according to the LHEF standard. It uses the current contents of the HEPRUP block.

```

<HEP common: public>+≡
    public :: heprup_write_lhef

<HEP common: procedures>+≡
    subroutine heprup_write_lhef (unit)
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit); if (u < 0) return
        write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
            IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
        do i = 1, NPRUP
            write (u, "(3(1x,ES17.10),1x,I0)") &
                XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
        end do
    end subroutine heprup_write_lhef

```

This routine is a complete dummy at the moment. It uses the current contents of the HEPRUP block. At the end, it should depend on certain input flags for the different ASCII event formats.

```

<HEP common: public>+≡
    public :: heprup_write_ascii

<HEP common: procedures>+≡
    subroutine heprup_write_ascii (unit)
        integer, intent(in), optional :: unit
        integer :: u, i
        u = given_output_unit (unit); if (u < 0) return
        write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
            IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
        do i = 1, NPRUP
            write (u, "(3(1x,ES17.10),1x,I0)") &
                XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
        end do
    end subroutine heprup_write_ascii

```

```

        end do
    end subroutine heprup_write_ascii

```

Run parameter input (LHEF)

In a LHEF file, the parameters are written in correct order on separate lines, but we should not count on the precise format. List-directed input should just work.

```

<HEP common: public>+≡
    public :: heprup_read_lhef

<HEP common: procedures>+≡
    subroutine heprup_read_lhef (u)
        integer, intent(in) :: u
        integer :: i
        read (u, *) &
            IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
        do i = 1, NPRUP
            read (u, *) &
                XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
        end do
    end subroutine heprup_read_lhef

```

32.5.6 The HEPEUP common block

```

<HEP common: common blocks>+≡
    common /HEPEUP/ &
        NUP, IDPRUP, XWGTUP, SCALUP, AQEDUP, AQCDUP, &
        IDUP, ISTUP, MOTHUP, ICOLUP, PUP, VTIMUP, SPINUP
    save /HEPEUP/

```

Initialization

Fill the event characteristics of the common block. The initialization sets only the number of particles and initializes the rest with default values. The other routine sets the optional parameters.

```

<HEP common: public>+≡
    public :: hepeup_init
    public :: hepeup_set_event_parameters

<HEP common: procedures>+≡
    subroutine hepeup_init (n_tot)
        integer, intent(in) :: n_tot
        NUP = n_tot
        IDPRUP = 0
        XWGTUP = 1
        SCALUP = -1
        AQEDUP = -1
        AQCDUP = -1
    end subroutine hepeup_init

```

```

subroutine hepeup_set_event_parameters &
  (proc_id, weight, scale, alpha_qed, alpha_qcd)
  integer, intent(in), optional :: proc_id
  real(default), intent(in), optional :: weight, scale, alpha_qed, alpha_qcd
  if (present (proc_id)) IDPRUP = proc_id
  if (present (weight)) XWGTUP = weight
  if (present (scale)) SCALUP = scale
  if (present (alpha_qed)) AQEDUP = alpha_qed
  if (present (alpha_qcd)) AQCDUP = alpha_qcd
end subroutine hepeup_set_event_parameters

```

Extract event information. The caller determines the parameters.

```

<HEP common: public>+≡
  public :: hepeup_get_event_parameters

<HEP common: procedures>+≡
  subroutine hepeup_get_event_parameters &
    (proc_id, weight, scale, alpha_qed, alpha_qcd)
    integer, intent(out), optional :: proc_id
    real(default), intent(out), optional :: weight, scale, alpha_qed, alpha_qcd
    if (present (proc_id)) proc_id = IDPRUP
    if (present (weight)) weight = XWGTUP
    if (present (scale)) scale = SCALUP
    if (present (alpha_qed)) alpha_qed = AQEDUP
    if (present (alpha_qcd)) alpha_qcd = AQCDUP
  end subroutine hepeup_get_event_parameters

```

Particle data

Below we need the particle status codes which are actually defined in the `subevents` module.

Set the entry for a specific particle. All parameters are set with the exception of lifetime and spin, where default values are stored.

```

```

Set the particle spin entry. We need the cosine of the angle of the spin axis with respect to the three-momentum of the parent particle.

If the particle has a full polarization density matrix given, we need the particle momentum and polarization as well as the mother-particle momentum. The polarization is transformed into a spin vector (which is sensible only for

spin-1/2 or massless particles), which then is transformed into the lab frame (by a rotation of the 3-axis to the particle momentum axis). Finally, we compute the scalar product of this vector with the mother-particle three-momentum.

This puts severe restrictions on the applicability of this definition, and Lorentz invariance is lost. Unfortunately, the Les Houches Accord requires this computation.

32.5.7 The HEPEVT common block

For the LEP Monte Carlos, a standard common block has been proposed in AKV89. We strongly recommend its use. (The description is an abbreviated transcription of AKV89, Vol. 3, pp. 327-330).

NMXHEP is the maximum number of entries:

```

<HEP common: variables>+≡
    integer, parameter :: NMXHEP = 4000

```

NEVHEP is normally the event number, but may take special values as follows:

0 the program does not keep track of event numbers. -1 a special initialization record. -2 a special final record.

```

<HEP common: variables>+≡
    integer :: NEVHEP

```

NHEP holds the number of entries for this event.

```

<HEP common: variables>+≡
    integer :: NHEP

```

The entry ISTHEP(N) gives the status code for the Nth entry, with the following semantics: 0 a null entry. 1 an existing entry, which has not decayed or fragmented. 2 a decayed or fragmented entry, which is retained for event history

information. 3 documentation line. 4- 10 reserved for future standards. 11-200 at the disposal of each model builder. 201- at the disposal of users.

```
<HEP common: variables>+≡
integer, dimension(NMXHEP) :: ISTHEP
```

The Particle Data Group has proposed standard particle codes, which are to be stored in IDHEP(N).

```
<HEP common: variables>+≡
integer, dimension(NMXHEP) :: IDHEP
```

JMOHEP(1,N) points to the mother of the Nth entry, if any. It is set to zero for initial entries. JMOHEP(2,N) points to the second mother, if any.

```
<HEP common: variables>+≡
integer, dimension(2, NMXHEP) :: JMOHEP
```

JDAHEP(1,N) and JDAHEP(2,N) point to the first and last daughter of the Nth entry, if any. These are zero for entries which have not yet decayed. The other daughters are stored in between these two.

```
<HEP common: variables>+≡
integer, dimension(2, NMXHEP) :: JDAHEP
```

In PHEP we store the momentum of the particle, more specifically this means that PHEP(1,N), PHEP(2,N), and PHEP(3,N) contain the momentum in the x , y , and z direction (as defined by the machine people), measured in GeV/c. PHEP(4,N) contains the energy in GeV and PHEP(5,N) the mass in GeV/ c^2 . The latter may be negative for spacelike partons.

```
<HEP common: variables>+≡
double precision, dimension(5, NMXHEP) :: PHEP
```

Finally VHEP is the place to store the position of the production vertex. VHEP(1,N), VHEP(2,N), and VHEP(3,N) contain the x , y , and z coordinate (as defined by the machine people), measured in mm. VHEP(4,N) contains the production time in mm/c.

```
<HEP common: variables>+≡
double precision, dimension(4, NMXHEP) :: VHEP
```

As an amendment to the proposed standard common block HEPEVT, we also have a polarisation common block HEPSPN, as described in AKV89. SHEP(1,N), SHEP(2,N), and SHEP(3,N) give the x , y , and z component of the spinvector s of a fermion in the fermions restframe.

Furthermore, we add the polarization of the corresponding outgoing particles:

```
<HEP common: variables>+≡
integer, dimension(NMXHEP) :: hepevt_pol
```

By convention, SHEP(4,N) is always 1. All this is taken from StdHep 4.06 manual and written using Fortran90 conventions.

```
<HEP common: common blocks>+≡
common /HEPEVT/ &
    NEVHEP, NHEP, ISTHEP, IDHEP, &
    JMOHEP, JDAHEP, PHEP, VHEP
save /HEPEVT/
```

Here we store HEPEVT parameters of the WHIZARD 1 realization which are not part of the HEPEVT common block.

```
<HEP common: variables>+≡
integer :: hepevt_n_out, hepevt_n_remnants
```

```
<HEP common: variables>+≡
double precision :: hepevt_weight, hepevt_function_value
double precision :: hepevt_function_ratio
```

Filling HEPEVT: If the event count is not provided, set NEVHEP to zero. If the event count is -1 or -2, the record corresponds to initialization and finalization, and the event is irrelevant.

Note that the event count may be larger than 2^{31} (2 GEvents). In that case, cut off the upper bits since NEVHEP is probably limited to default integer.

```
<HEP common: public>+≡
public :: hepevt_init
public :: hepevt_set_event_parameters

<HEP common: procedures>+≡
subroutine hepevt_init (n_tot, n_out)

end do

end subroutine hepeup_write_lha

```

This routine writes event output according to the HEPEVT standard. It uses the current contents of the HEPEVT block and some additional parameters according to the standard in WHIZARD 1. For the long ASCII format, the value of the sample function (i.e. the product of squared matrix element, structure functions and phase space factor is printed out). The option of reweighting matrix elements with respect to some reference cross section is not implemented in WHIZARD 2 for this event format, therefore the second entry in the long ASCII format (the function ratio) is always one. The ATHENA format is an implementation of the HEPEVT format that is readable by the ATLAS ATHENA software framework. It is very similar to the WHIZARD 1 HEPEVT format, except that it contains an event counter, a particle counter inside the event, and has the HEPEVT ISTHEP status before the PDG code. The MOKKA format is a special ASCII format that contains the information to be parsed to the MOKKA LC fast simulation software.

        end do
    end subroutine hepeup_read_lhef

```

32.5.11 Data Transfer: particle sets

The WHIZARD format for handling particle data in events is `particle_set_t`. We have to interface this to the common blocks.

We first create a new particle set that contains only the particles that are supported by the LHEF format. These are: beam, incoming, resonant, outgoing. We drop particles with unknown, virtual or beam-remnant status.

From this set we fill the common block. Event information such as process ID and weight is not transferred here; this has to be done by the caller. The spin information is set only if the particle has a unique mother, and if its polarization is fully defined.

```

<HEP common: public>+≡
    public :: hepeup_from_particle_set
<HEP common: procedures>+≡
    subroutine hepeup_from_particle_set (particle_set, keep_beams)
        type(particle_set_t), intent(in), target :: particle_set
        logical, intent(in), optional :: keep_beams
        type(particle_t), pointer :: prt
        type(particle_set_t), target :: pset_hepevt
        integer :: i, n_parents
        integer, dimension(1) :: i_mother
        call particle_set_to_hepevt_form (particle_set, pset_hepevt, keep_beams)
        call hepeup_init (pset_hepevt%n_tot)
        do i = 1, pset_hepevt%n_tot

```

```

prt => pset_hepevt%prt(i)
call hepeup_set_particle (i, &
    particle_get_pdg (prt), &
    particle_get_status (prt), &
    particle_get_parents (prt), &
    particle_get_color (prt), &
    particle_get_momentum (prt), &
    particle_get_p2 (prt))
n_parents = particle_get_n_parents (prt)
if (n_parents == 1) then
    i_mother = particle_get_parents (prt)
    select case (particle_get_polarization_status (prt))
    case (PRT_GENERIC_POLARIZATION)
        call hepeup_set_particle_spin (i, &
            particle_get_momentum (prt), &
            particle_get_polarization (prt), &
            particle_get_momentum (pset_hepevt%prt(i_mother(1))))
    end select
end if
end do
call particle_set_final (pset_hepevt)
end subroutine hepeup_from_particle_set

```

Input. The particle set should be allocated properly, but we replace the particle contents.

If there are no beam particles in the event, we try to reconstruct beam particles and beam remnants. We assume for simplicity that the beam particles, if any, are the first two particles. If they are absent, the first two particles should be the incoming partons.

```

<HEP common: public>+≡
    public :: hepeup_to_particle_set

<HEP common: procedures>+≡
    subroutine hepeup_to_particle_set &

  end do
else
  call handle_beams (prt)
end if
call particle_set_replace (particle_set, prt)
end subroutine hepeup_to_particle_set

```

Beams and beam remnants require a special handling. WHIZARD's interactions are set up such that in the list of children of beam particles, the remnant comes before the interacting parton. To enforce this, we may have to reorder things.

The beam particles will always be the first two particles.

(HEP common: procedures)+≡

```

subroutine handle_beams (prt)
  type(particle_t), dimension(:), intent(inout) :: prt
  integer :: i
  integer, dimension(2) :: child
  do i = 1, 2

```

```

        select case (particle_get_status (prt(i)))
        case (PRT_BEAM)
            child = particle_get_children (prt(i))
            if (particle_get_status (prt(child(2))) == PRT_BEAM_REMNANT) then
                call particle_set_children (prt(i), child([2,1]))
            end if
        end select
    end do
end subroutine handle_beams

```

The HEPEVT common block is quite similar, but does contain less information, e.g. no color flows (it was LEP time). The spin information is set only if the particle has a unique mother, and if its polarization is fully defined.

```

    end subroutine hepevt_from_particle_set

```

32.6 HEP Common and Events

This is a separate module that manages data exchange between the common blocks and `event_t` objects. We separate this from the previous module in order to avoid a circular module dependency. It also contains the functions necessary for communication between `hepmc_event_t` and `event_t` objects.

```

<hep_events.f90>≡
    <File header>

    module hep_events

        use kinds

```

```

use io_units
use diagnostics

use model_data
use particles
use processes
use hep_common
use hepmc_interface
use events

<Standard module head>

<HEP events: public>

contains

<HEP events: procedures>

end module hep_events

```

32.6.1 Data Transfer: events

Fill the HEPEUP block, given a WHIZARD event object.

```

<HEP events: public>≡
    public :: hepeup_from_event

<HEP events: procedures>≡
    subroutine hepeup_from_event (event, keep_beams, process_index)
        type(event_t), intent(in), target :: event
        logical, intent(in), optional :: keep_beams
        integer, intent(in), optional :: process_index
        type(particle_set_t), pointer :: particle_set
        real(default) :: scale, alpha_qcd
        if (event%has_particle_set ()) then
            particle_set => event%get_particle_set_ptr ()
            call hepeup_from_particle_set (particle_set, keep_beams)
            if (present (process_index)) &
                call hepeup_set_event_parameters (proc_id = process_index)
            scale = event%get_fac_scale ()
            if (scale /= 0) &
                call hepeup_set_event_parameters (scale = scale)
            alpha_qcd = event%get_alpha_s ()
            if (alpha_qcd /= 0) &
                call hepeup_set_event_parameters (alpha_qcd = alpha_qcd)
            if (event%weight_prc_is_known) then
                call hepeup_set_event_parameters (weight = event%weight_prc)
            else
                call msg_bug ("HEPEUP: process weight is unknown")
            end if
        else
            call msg_bug ("HEPEUP: event incomplete")
        end if
    end subroutine hepeup_from_event

```

Reverse.

Note: The current implementation sets the particle set of the hard process and is therefore not useful if the event on file is dressed. This should be reconsidered.

Note: setting of scale or alpha is not yet supported by the `event_t` object. Ticket #628.

```
<HEP events: public>+≡
  public :: hepeup_to_event

<HEP events: procedures>+≡
  subroutine hepeup_to_event &
    (event, fallback_model, process_index, recover_beams)

Input an event. Upon input of `i_prc`, we can just read in the whole HEPEUP common block. These data are known to come first. The `i_prc` value can be deduced from the IDPRUP value by a table lookup.

Reading the common block bypasses the `cstream` which accesses the input unit. This is consistent with the LHEF specification. After the common-block data have been swallowed, we can resume reading from stream.

We don't catch actual I/O errors. However, we return a negative value in `iostat` if we reached the terminating `</LesHouchesEvents>` tag.

Since we have already read the event information from file, this input routine can transfer the common-block contents to the event record. Also, we read any further information in the event record.

Since LHEF doesn't give this information, we must assume that the MCI group, term, and channel can all be safely set to 1. This works if there is only one MCI group and term. The channel doesn't matter for the matrix element.

32.7.5 Version-Specific Code: 1.0

In version 1.0, the init tag contains just HEPUP data. While a `cstream` is connected to the input unit, we bypass it temporarily for the purpose of reading the HEPUP contents. This is consistent with the LHEF standard.

This routine does not read the closing tag of the init block.

```

<EIO LHEF: eio_lhef: TBP>+≡
  procedure :: read_init_10 => eio_lhef_read_init_10
<EIO LHEF: procedures>+≡
subroutine eio_lhef_read_init_10 (eio, data)
  class(eio_lhef_t), intent(in) :: eio
  type(event_sample_data_t), intent(out) :: data
  integer :: n_proc, i
  call heprup_read_lhef (eio%unit)
  call heprup_get_run_parameters (n_processes = n_proc)
  call data%init (n_proc)
  data%n_beam = 2
  call heprup_get_run_parameters ( &
    unweighted = data%unweighted, &
    negative_weights = data%negative_weights, &
    beam_pdg = data%pdg_beam, &
    beam_energy = data%energy_beam)
  if (data%unweighted) then
    data%norm_mode = NORM_UNIT
  else
    data%norm_mode = NORM_SIGMA
  end if
  do i = 1, n_proc
    call heprup_get_process_parameters (i, &

```

```

        process_id = data%proc_num_id(i), &
        cross_section = data%cross_section(i), &
        error = data%error(i))
    end do
end subroutine eio_lhef_read_init_10

```

32.7.6 Version-Specific Code: 2.0

This is the init information for the 2.0 format, after the HEPUP data. We have the following tags:

- **generator** Generator name and version.
- **xsecinfo** Cross section and weights data. We have the total cross section and number of events (assuming that the event file is intact), but information on minimum and maximum weights is not available before the file is complete. We just write the mandatory tags. (Note that the default values of the other tags describe a uniform unit weight, but we can determine most values only after the sample is complete.)
- **cutsinfo** This optional tag is too specific to represent the possibilities of WHIZARD, so we skip it.
- **procinfo** This optional tag is useful for giving details of NLO calculations. Skipped.
- **mergetype** Optional, also not applicable.

```

<EIO LHEF: eio_lhef: TBP>+≡
  procedure :: write_init_20 => eio_lhef_write_init_20

<EIO LHEF: procedures>+≡
  subroutine eio_lhef_write_init_20 (eio, data)
    class(eio_lhef_t), intent(in) :: eio
    type(event_sample_data_t), intent(in) :: data
    integer :: u
    u = eio%unit
    call eio%tag_generator%write (u)
    write (u, "(A)", advance="no") "WHIZARD"
    call eio%tag_generator%close (u); write (u, *)
    call eio%tag_xsecinfo%write (u); write (u, *)
  end subroutine eio_lhef_write_init_20

```

When reading the init block, we first call the 1.0 routine that fills HEPUP. Then we consider the possible tags. Only the **generator** and **xsecinfo** tags are of interest. We skip everything else except for the closing tag.

```

<EIO LHEF: eio_lhef: TBP>+≡

32.7.8 Auxiliary

Create a string from a number. We use fixed format for the reals and variable format for integers.

```
<EIO LHEF: interfaces>+≡
  interface str
    module procedure str_int, str_real
  end interface

<EIO LHEF: procedures>+≡
  function str_int (i) result (s)
    integer, intent(in) :: i
    type(string_t) :: s
    character(32) :: buffer
    write (buffer, "(I0)") i
    s = var_str (trim (buffer))
  end function str_int

  function str_real (x) result (s)
    real(default), intent(in) :: x
    type(string_t) :: s
    character(32) :: buffer
    write (buffer, "(ES17.10)") x
    s = var_str (trim (adjustl (buffer)))
  end function str_real
```

Auxiliary: Read real, integer, string value.

```
<EIO LHEF: procedures>+≡
  function read_rval (s) result (rval)
    type(string_t), intent(in) :: s
    real(default) :: rval
    character(80) :: buffer
    buffer = s
    read (buffer, *) rval
  end function read_rval

  function read_ival (s) result (ival)
    type(string_t), intent(in) :: s
    integer :: ival
    character(80) :: buffer
    buffer = s
    read (buffer, *) ival
  end function read_ival
```

32.7.9 Unit tests

```
<EIO LHEF: public>+≡
  public :: eio_lhef_test
```

```

<EIO LHEF: tests>≡
  subroutine eio_lhef_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
  <EIO LHEF: execute tests>
  end subroutine eio_lhef_test

```

Version 1.0 Output

We test the implementation of all I/O methods. We start with output according to version 1.0.

```

32.8 HepMC Output

The HepMC event record is standardized. It is an ASCII format. We try our best at using it for both input and output.

`<eio_hepmc.f90>`≡
<File header>

```

module eio_hepmc

  use kinds
  use io_units
<Use strings>
  use unit_tests
  use diagnostics
  use os_interface
  use lorentz
  use model_data
  use particles
  use subevents
  use beams
  use processes
  use events
  use hep_events
  use eio_data

```

```

    use eio_base
    use hepmc_interface
    use models

    <Standard module head>

    <EIO HepMC: public>

    <EIO HepMC: types>

    <EIO HepMC: interfaces>

contains

    <EIO HepMC: procedures>

    <EIO HepMC: tests>

end module eio_hepmc

```

32.8.1 Type

A type `hepmc_event` is introduced as container to store HepMC event data, particularly for splitting the reading into read out of the process index and the proper event data.

```

<EIO HepMC: public>≡
    public :: eio_hepmc_t

<EIO HepMC: types>≡
    type, extends (eio_t) :: eio_hepmc_t
        logical :: writing = .false.
        logical :: reading = .false.
        logical :: keep_beams = .false.
        logical :: recover_beams = .false.
        type(hepmc_iostream_t) :: iostream
        type(hepmc_event_t) :: hepmc_event
        integer, dimension(:), allocatable :: proc_num_id
    contains
        <EIO HepMC: eio hepmc: TBP>
    end type eio_hepmc_t

```

32.8.2 Specific Methods

Set parameters that are specifically used with HepMC.

```

<EIO HepMC: eio hepmc: TBP>≡
    procedure :: set_parameters => eio_hepmc_set_parameters

<EIO HepMC: procedures>≡
    subroutine eio_hepmc_set_parameters (eio, keep_beams, &
        recover_beams, extension)
        class(eio_hepmc_t), intent(inout) :: eio
        logical, intent(in), optional :: keep_beams
    end subroutine

```

```

logical, intent(in), optional :: recover_beams
type(string_t), intent(in), optional :: extension
if (present (keep_beams)) eio%keep_beams = keep_beams
if (present (recover_beams)) eio%recover_beams = recover_beams
if (present (extension)) then
    eio%extension = extension
else
    eio%extension = "hepmc"
end if
end subroutine eio_hepmc_set_parameters

```

32.8.3 Common Methods

Output. This is not the actual event format, but a readable account of the current object status.

```

32.10 ASCII File Formats

Here, we implement several ASCII file formats. It is possible to switch between them using flags.

```
<eio_ascii.f90>≡  
  <File header>  
  
  module eio_ascii  
  
    use kinds  
    use io_units  
    <Use strings>  
    use unit_tests  
    use diagnostics  
  
    use lorentz  
    use model_data  
    use particles  
    use beams  
    use processes  
    use events  
    use eio_data  
    use eio_base  
    use hep_common  
    use hep_events  
  
    <Standard module head>  
  
    <EIO ascii: public>  
  
    <EIO ascii: types>  
  
    contains  
  
    <EIO ascii: procedures>  
  
    <EIO ascii: tests>  
  
  end module eio_ascii
```

32.10.1 Type

```
<EIO ascii: public>≡  
  public :: eio_ascii_t  
  
<EIO ascii: types>≡  
  type, abstract, extends (eio_t) :: eio_ascii_t  
    logical :: writing = .false.  
    integer :: unit = 0  
    logical :: keep_beams = .false.

32.11 STDHEP File Formats

Here, we implement the two existing STDHEP file formats, one based on the HEPRUP/HEPEUP common blocks, the other based on the HEPEVT common block. The second one is actually the standard STDHEP format.

`<eio_stdhep.f90>`≡
<File header>

```

module eio_stdhep

    use kinds
    use io_units
    <Use strings>
    use unit_tests
    use diagnostics

    use lorentz
    use model_data
    use particles
    use beams
    use processes
    use events
    use eio_data
    use eio_base

```

```

    use hep_common
    use hep_events

    <Standard module head>

    <EIO stdhep: public>

    <EIO stdhep: types>

    <EIO stdhep: variables>

    contains

    <EIO stdhep: procedures>

    <EIO stdhep: tests>

    end module eio_stdhep

```

32.11.1 Type

```

<EIO stdhep: public>≡
    public :: eio_stdhep_t

<EIO stdhep: types>≡
    type, abstract, extends (eio_t) :: eio_stdhep_t
        logical :: writing = .false.
        logical :: reading = .false.
        integer :: unit = 0
        logical :: keep_beams = .false.
        integer(i64) :: n_events_expected = 0
    contains
        <EIO stdhep: eio stdhep: TBP>
    end type eio_stdhep_t

<EIO stdhep: public>+≡
    public :: eio_stdhep_hepevt_t

<EIO stdhep: types>+≡
    type, extends (eio_stdhep_t) :: eio_stdhep_hepevt_t
    end type eio_stdhep_hepevt_t

<EIO stdhep: public>+≡
    public :: eio_stdhep_hepeup_t

<EIO stdhep: types>+≡
    type, extends (eio_stdhep_t) :: eio_stdhep_hepeup_t
    end type eio_stdhep_hepeup_t

```

32.11.2 Specific Methods

Set parameters that are specifically used with STDHEP file formats.

```

<EIO stdhep: eio stdhep: TBP>≡

```

```

        procedure :: set_parameters => eio_stdhep_set_parameters
    <EIO stdhep: procedures>≡
        subroutine eio_stdhep_set_parameters (eio, keep_beams, extension)
            class(eio_stdhep_t), intent(inout) :: eio
            logical, intent(in), optional :: keep_beams
            type(string_t), intent(in), optional :: extension
            if (present (keep_beams)) eio%keep_beams = keep_beams
            if (present (extension)) then
                eio%extension = extension
            else
                select type (eio)
                type is (eio_stdhep_hepevt_t)
                    eio%extension = "hep"
                type is (eio_stdhep_hepeup_t)
                    eio%extension = "up.hep"
                end select
            end if
        end subroutine eio_stdhep_set_parameters

```

32.11.3 Common Methods

Output. This is not the actual event format, but a readable account of the current object status.

```

    <EIO stdhep: eio stdhep: TBP>+≡
        procedure :: write => eio_stdhep_write
    <EIO stdhep: procedures>+≡

32.12 Event Weight Output

This is an output-only format. For each event, we print the indices that identify process, process part (MCI group), and term. As numerical information we print the squared matrix element (trace) and the event weight.

```

<eio_weights.f90>≡

    call msg_bug ("Weight stream: in-out switch not supported")
    if (present (success)) success = .false.
  end subroutine eio_weights_switch_inout

```

Output an event. Write first the event indices, then weight and two values of the squared matrix element: `sqme_ref` is the value stored in the event record, and `sqme_prc` is the one stored in the process instance. (They can differ: when recalculating, the former is read from file and the latter is the result of the new calculation.)

For the alternative entries, the `sqme` value is always obtained by a new calculation, and thus qualifies as `sqme_prc`.

```

<SLHA: parameters>

<SLHA: variables>

```
save
```

```
contains

<SLHA: procedures>

<SLHA: tests>

end module slha_interface
```

33.0.5 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

```
<SLHA: parameters>≡
    integer, parameter :: MODE_SKIP = 0, MODE_DATA = 1, MODE_INFO = 2

<SLHA: procedures>≡
    subroutine slha_preprocess (stream, ifile)
        type(stream_t), intent(inout), target :: stream
        type(ifile_t), intent(out) :: ifile
        type(string_t) :: buffer, line, item
        integer :: iostat
        integer :: mode
        mode = MODE
        SCAN_FILE: do
            call stream_get_record (stream, buffer, iostat)
            select case (iostat)
            case (0)
                call split (buffer, line, "#")
                if (len_trim (line) == 0) cycle SCAN_FILE
                select case (char (extract (line, 1, 1)))
                case ("B", "b")
                    mode = check_block_handling (line)
                    call ifile_append (ifile, line // "$")
                case ("D", "d")
                    mode = MODE_DATA

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

```

<SLHA: public>+=
    public :: lexer_init_slha

SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is not defined in the block, we use the previous value from the model variable list. For the basic parameters we have to do a small recalculation, since SLHA uses the G_F - α - m_Z scheme, while WHIZARD derives them from G_F , m_W , and m_Z .

33.0.9 Parser

Read a SLHA file from stream, including preprocessing, and make up a parse tree.

```

<SLHA: procedures>+=
subroutine slha_parse_stream (stream, parse_tree)
    type(stream_t), intent(inout), target :: stream
    type(parse_tree_t), intent(out) :: parse_tree
    type(ifile_t) :: ifile
    type(lexer_t) :: lexer
    type(stream_t), target :: stream_tmp
    call slha_preprocess (stream, ifile)
    call stream_init (stream_tmp, ifile)
    call lexer_init_slha (lexer)
    call lexer_assign_stream (lexer, stream_tmp)
    call parse_tree_init (parse_tree, syntax_slha, lexer)
    call lexer_final (lexer)
    call stream_final (stream_tmp)
    call ifile_final (ifile)
end subroutine slha_parse_stream

```

Read a SLHA file chosen by name. Check first the current directory, then the directory where SUSY input files should be located.

```

<SLHA: procedures>+=
subroutine slha_parse_file (file, os_data, parse_tree)
    type(string_t), intent(in) :: file
    type(os_data_t), intent(in) :: os_data
    type(parse_tree_t), intent(out) :: parse_tree
    logical :: exist
    type(string_t) :: filename
    type(stream_t), target :: stream

end subroutine slha_parse_file

```

33.0.10 API

Read the SLHA file, parse it, and interpret the parse tree. The model parameters retrieved from the file will be inserted into the appropriate model, which is loaded and modified in the background. The pointer to this model is returned as the last argument.

```

<SLHA: public>+=
    public :: slha_read_file

<SLHA: procedures>+=
    subroutine slha_read_file &
        (file, os_data, model, input, spectrum, decays)

Chapter 34

NLO infrastructure

34.1 BLHA interface

These modules implement the communication with one loop matrix element providers according to the Binoth LesHouches Accord Interface. The actual matrix element(s) are loaded as a dynamic library.

The module is split into a configuration interface which manages configuration and handles the request and contract files, a module which interfaces the OLP matrix elements and a driver.

```

34.1.2 OLP matrix element interface

The prototypes of the OLP functions.

(BLHA interface: interfaces)≡

```

abstract interface
  subroutine ext_olp_start (file, status) bind(c)
    import
    character(c_char), dimension(*), intent(in) :: file
    integer(c_int), intent(out) :: status
  end subroutine ext_olp_Start

  subroutine ext_olp_evalsubprocess &
    (label, momenta, scale, parameters, amp) bind(c)
    import
    integer(c_int), intent(in), value :: label
    real(c_double), dimension(*), intent(in) :: momenta
    real(c_double), intent(in), value :: scale
    real(c_double), dimension(*), intent(in) :: parameters
    real(c_double), dimension(*), intent(out) :: amp

```

```

end subroutine ext_olp_evalsubprocess

subroutine ext_olp_finalize () bind(c)
end subroutine ext_olp_finalize

subroutine ext_olp_option (assignment, status) bind(c)
  import
  character(c_char), dimension(*), intent(in) :: assignment
  integer(c_int), intent(out) :: status
end subroutine ext_olp_option
end interface

```

The OLP library is encapsulated together with the configuration in derived type:

```

<BLHA interface: public>≡
  public :: blha_olp_t

<BLHA interface: types>≡
  type :: blha_olp_t
  private
  type(blha_configuration_t) :: cfg
  type(string_t) :: library
  integer :: n_in, n_out, n_flv, n_hel, n_col
  integer, dimension(:,:), allocatable :: flv_state
  logical :: color_summed = .true., flavor_summed = .true.
  logical :: loaded = .false.
  type(dlaccess_t) :: lib_handle
  procedure(ext_olp_start), pointer, nopass :: olp_start => null ()
  procedure(ext_olp_evalsubprocess), pointer, nopass :: &
    olp_evalsubprocess => null ()
  procedure(ext_olp_finalize), pointer, nopass :: olp_finalize => null ()
  procedure(ext_olp_option), pointer, nopass :: olp_option => null ()
end type blha_olp_t

```

Init the `blha_olp_t` object and try to dlopen the library.

```

  end subroutine blha_test

```

Chapter 35

Integration and simulation

This layer of modules is just below the top-level API. We lay out specific data types for integration and simulation and implement the corresponding algorithms as methods acting on them. This helps to keep the command-level implementation concise and simple.

35.1 User-controlled File I/O

The SINDARIN language includes commands that write output to file (input may be added later). We identify files by their name, and manage the unit internally. We need procedures for opening, closing, and printing files.

```
(user_files.f90)≡  
  <File header>  
  
  module user_files  
  
    <Use strings>  
    use io_units  
    use diagnostics  
    use ifiles  
    use analysis  
  
    <Standard module head>  
  
    <User files: public>  
  
    <User files: types>  
  
    <User files: interfaces>  
  
    contains  
  
    <User files: procedures>  
  
  end module user_files
```

35.1.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

```
<User files: types>≡
  type :: file_t
  private
  type(string_t) :: name
  integer :: unit = -1
  logical :: reading = .false.
  logical :: writing = .false.
  type(file_t), pointer :: prev => null ()
  type(file_t), pointer :: next => null ()
end type file_t
```

The initializer opens the file.

```
<User files: procedures>≡
  subroutine file_init (file, name, action, status, position)
    type(file_t), intent(out) :: file
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    file%unit = free_unit ()
    file%name = name
    open (unit = file%unit, file = char (file%name), &
          action = action, status = status, position = position)
    select case (action)
    case ("read")
      file%reading = .true.
    case ("write")
      file%writing = .true.
    case ("readwrite")
      file%reading = .true.
      file%writing = .true.
    end select
  end subroutine file_init
```

The finalizer closes it.

```
<User files: procedures>+≡
  subroutine file_final (file)
    type(file_t), intent(inout) :: file
    close (unit = file%unit)
    file%unit = -1
  end subroutine file_final
```

Check if a file is open with correct status.

```
<User files: procedures>+≡
  function file_is_open (file, action) result (flag)
    logical :: flag
    type(file_t), intent(in) :: file
    character(*), intent(in) :: action
    select case (action)
    case ("read")
```

```

        flag = file%reading
    case ("write")
        flag = file%writing
    case ("readwrite")
        flag = file%reading .and. file%writing
    case default
        call msg_bug ("Checking file '" // char (file%name) &
            // "' : illegal action specifier")
    end select
end function file_is_open

```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the `advancing` option.

<User files: procedures>+≡

```

subroutine file_write_string (file, string, advancing)
    type(file_t), intent(in) :: file
    type(string_t), intent(in), optional :: string
    logical, intent(in), optional :: advancing
    if (file%writing) then
        if (present (string)) then
            if (present (advancing)) then
                if (advancing) then
                    write (file%unit, "(A)") char (string)
                else
                    write (file%unit, "(A)", advance="no") char (string)
                end if
            else
                write (file%unit, "(A)") char (string)
            end if
        else
            write (file%unit, *)
        end if
    else
        call msg_error ("Writing to file: File '" // char (file%name) &
            // "' is not open for writing.")
    end if
end subroutine file_write_string

```

Write a whole ifile, line by line.

<User files: procedures>+≡

```

subroutine file_write_ifile (file, ifile)
    type(file_t), intent(in) :: file
    type(ifile_t), intent(in) :: ifile
    type(line_p) :: line
    call line_init (line, ifile)
    do while (line_is_associated (line))
        call file_write_string (file, line_get_string_advance (line))
    end do
end subroutine file_write_ifile

```

Write an analysis object (or all objects) to an open file.

<User files: procedures>+≡

```

subroutine file_write_analysis (file, tag)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: tag
  if (file%writing) then
    if (present (tag)) then
      call analysis_write (tag, unit = file%unit)
    else
      call analysis_write (unit = file%unit)
    end if
  else
    call msg_error ("Writing analysis to file: File ' " // char (file%name) &
      // "' is not open for writing.")
  end if
end subroutine file_write_analysis

```

35.1.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

```

<User files: public>≡
  public :: file_list_t

<User files: types>+≡
  type :: file_list_t
    type(file_t), pointer :: first => null ()
    type(file_t), pointer :: last => null ()
  end type file_list_t

```

There is no initialization routine, but a finalizer which deletes all:

```

<User files: public>+≡
  public :: file_list_final

<User files: procedures>+≡
  subroutine file_list_final (file_list)
    type(file_list_t), intent(inout) :: file_list
    type(file_t), pointer :: current
    do while (associated (file_list%first))
      current => file_list%first
      file_list%first => current%next
      call file_final (current)
      deallocate (current)
    end do
    file_list%last => null ()
  end subroutine file_list_final

```

Find an entry in the list. Return null pointer on failure.

```

<User files: procedures>+≡
  function file_list_get_file_ptr (file_list, name) result (current)
    type(file_t), pointer :: current
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    current => file_list%first

```

```

do while (associated (current))
  if (current%name == name) return
  current => current%next
end do
end function file_list_get_file_ptr

```

Check if a file is open, public version:

```

<User files: public>+≡
  public :: file_list_is_open

<User files: procedures>+≡
  function file_list_is_open (file_list, name, action) result (flag)
    logical :: flag
    type(file_list_t), intent(in) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action
    type(file_t), pointer :: current
    current => file_list_get_file_ptr (file_list, name)
    if (associated (current)) then
      flag = file_is_open (current, action)
    else
      flag = .false.
    end if
  end function file_list_is_open

```

Append a new file entry, i.e., open this file. Error if it is already open.

```

<User files: public>+≡
  public :: file_list_open

<User files: procedures>+≡
  subroutine file_list_open (file_list, name, action, status, position)
    type(file_list_t), intent(inout) :: file_list
    type(string_t), intent(in) :: name
    character(len=*), intent(in) :: action, status, position
    type(file_t), pointer :: current
    if (.not. associated (file_list_get_file_ptr (file_list, name))) then
      allocate (current)
      call msg_message ("Opening file '" // char (name) // "' for output")
      call file_init (current, name, action, status, position)
      if (associated (file_list%last)) then
        file_list%last%next => current
        current%prev => file_list%last
      else
        file_list%first => current
      end if
      file_list%last => current
    else
      call msg_error ("Opening file: File '" // char (name) &
        // "' is already open.")
    end if
  end subroutine file_list_open

```

Delete a file entry, i.e., close this file. Error if it is not open.

```

<User files: public>+≡
    public :: file_list_close

<User files: procedures>+≡
    subroutine file_list_close (file_list, name)
        type(file_list_t), intent(inout) :: file_list
        type(string_t), intent(in) :: name
        type(file_t), pointer :: current
        current => file_list_get_file_ptr (file_list, name)
        if (associated (current)) then
            if (associated (current%prev)) then
                current%prev%next => current%next
            else
                file_list%first => current%next
            end if
            if (associated (current%next)) then
                current%next%prev => current%prev
            else
                file_list%last => current%prev
            end if
            call msg_message ("Closing file '" // char (name) // "' for output")
            call file_final (current)

35.2.1 Strategy for models and variables

The program manages its data via a main `rt_data_t` object. During program flow, various commands create and use local `rt_data_t` objects. Those transient blocks contain either pointers to global object or local copies which are deleted after use.

Each `rt_data_t` object contains a variable list component. This lists holds (local copies of) all kinds of intrinsic or user-defined variables. The variable list is linked to the variable list contained in the local process library. This, in turn, is linked to the variable list of the `rt_data_t` context, and so on.

A variable lookup will thus be recursively delegated to the linked variable lists, until a match is found. When modifying a variable which is not yet local, the program creates a local copy and uses this afterwards. Thus, when the local `rt_data_t` object is deleted, the context value is recovered.

Models are kept in a model list which is separate from the variable list. Otherwise, they are treated in a similar manner: the local list is linked to the context model list. Model lookup is thus recursively delegated. When a model or any part of it is modified, the model is copied to the local `rt_data_t` object, so the context model is not modified. Commands such as `integrate` will create their own copy of the current model (and of the current variable list) at the point where they are executed.

When a model is encountered for the first time, it is read from file. The reading is automatically delegated to the global context. Thus, this master copy survives until the main `rt_data_t` object is deleted, at program completion.

If there is a currently active model, its variable list is linked to the main variable list. Variable lookups will then start from the model variable list. When the current model is switched, the new active model will get this link instead. Consequently, a change to the current model is kept as long as this model has a local copy; it survives local model switches. On the other hand, a parameter change in the current model doesn't affect any other model, even if the parameter name is identical.

35.2.2 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have not been compiled into evaluation trees but saved for later use). We collect them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

```

<RT data: types>≡
  type :: rt_parse_nodes_t
    type(parse_node_t), pointer :: cuts_lexpr => null ()
    type(parse_node_t), pointer :: scale_expr => null ()
    type(parse_node_t), pointer :: fac_scale_expr => null ()
    type(parse_node_t), pointer :: ren_scale_expr => null ()
    type(parse_node_t), pointer :: weight_expr => null ()
    type(parse_node_t), pointer :: selection_lexpr => null ()
    type(parse_node_t), pointer :: reweight_expr => null ()
    type(parse_node_t), pointer :: analysis_lexpr => null ()
    type(parse_node_p), dimension(:), allocatable :: alt_setup
  contains
    <RT data: rt parse nodes: TBP>
  end type rt_parse_nodes_t

```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

```

<RT data: rt parse nodes: TBP>≡
  procedure :: clear => rt_parse_nodes_clear

```

```

<RT data: procedures>≡
subroutine rt_parse_nodes_clear (rt_pn, name)
  class(rt_parse_nodes_t), intent(inout) :: rt_pn

```

35.2.7 Local copies

This is done at compile time when a local copy of runtime data is needed: Link the variable list and initialize all derived parameters. This allows for synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their targets.

```

<RT data: rt data: TBP>+≡
    procedure :: local_init => rt_data_local_init

<RT data: procedures>+≡
    subroutine rt_data_local_init (local, global, env)
        class(rt_data_t), intent(inout), target :: local
        type(rt_data_t), intent(in), target :: global
        integer, intent(in), optional :: env
        local%context => global
        call local%process_stack%link (global%process_stack)
        call local%process_stack%init_var_list (local%var_list)
        call local%process_stack%link_var_list (global%var_list)
    end subroutine

```

```

call var_list_append_string &
  (local%var_list, var_str ("$_model_name"), var_str (""), &
   intrinsic=.true.)
call local%init_pointer_variables ()
local%fallback_model => global%fallback_model
local%os_data = global%os_data
local%logfile = global%logfile
call local%model_list%link (global%model_list)
local%model => global%model
if (associated (local%model)) then
  call local%model%link_var_list (local%var_list)
end if
end subroutine rt_data_local_init

```

These variables point to objects which get local copies:

```

<RT data: rt data: TBP>+≡
  procedure :: init_pointer_variables => rt_data_init_pointer_variables

<RT data: procedures>+≡
  subroutine rt_data_init_pointer_variables (local)
    class(rt_data_t), intent(inout), target :: local
    logical, target, save :: known = .true.
    call var_list_append_string_ptr &
      (local%var_list, var_str ("$_fc"), local%os_data%fc, known, &
       intrinsic=.true.)
    call var_list_append_string_ptr &
      (local%var_list, var_str ("$_fcflags"), local%os_data%fcflags, known, &
       intrinsic=.true.)
  end subroutine rt_data_init_pointer_variables

```

This is done at execution time: Copy data, transfer pointers. `local` has intent(inout) because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: activate => rt_data_activate

<RT data: procedures>+≡
  subroutine rt_data_activate (local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), pointer :: global
    global => local%context
    if (associated (global)) then
      local%lexer => global%lexer
      call global%copy_globals (local)
    end if
  end subroutine rt_data_activate

```

```

local%os_data = global%os_data
local%logfile = global%logfile
if (associated (global%prclib)) then
  local%prclib => &
    local%prclib_stack%get_library_ptr (global%prclib%get_name ())
end if
call local%import_values ()
call local%process_stack%link (global%process_stack)
local%it_list = global%it_list
local%beam_structure = global%beam_structure
local%pn = global%pn
if (allocated (local%sample_fmt)) deallocate (local%sample_fmt)
if (allocated (global%sample_fmt)) then
  allocate (local%sample_fmt (size (global%sample_fmt)), &
    source = global%sample_fmt)
end if
local%out_files => global%out_files
local%model => global%model
local%model_is_copy = .false.
else if (.not. associated (local%model)) then
  local%model => local%preload_model
  local%model_is_copy = .false.
end if
if (associated (local%model)) then
  call local%model%link_var_list (local%var_list)
  call var_list_set_string (local%var_list, var_str ("$model_name"), &
    local%model%get_name (), is_known = .true.)
else
  call var_list_set_string (local%var_list, var_str ("$model_name"), &
    var_str (""), is_known = .false.)
end if
end subroutine rt_data_activate

```

Restore the previous state of data, without actually finalizing the local environment. We also clear the local process stack. Some local modifications (model list and process library stack) are communicated to the global context, if there is any.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!). The local variables are also kept.

```

<RT data: rt data: TBP>+≡
  procedure :: deactivate => rt_data_deactivate

<RT data: procedures>+≡
  subroutine rt_data_deactivate (local, global, keep_local)
    class(rt_data_t), intent(inout), target :: local
    class(rt_data_t), intent(inout), optional, target :: global
    logical, intent(in), optional :: keep_local
    type(string_t) :: global_model, local_model
    logical :: same_model, delete
    delete = .true.; if (present (keep_local)) delete = .not. keep_local
    if (present (global)) then

```

```

    if (associated (global%model) .and. associated (local%model)) then
        global_model = global%model%get_name ()
        local_model = local%model%get_name ()
        same_model = global_model == local_model
    else
        same_model = .false.
    end if
    if (delete) then
        call local%process_stack%clear ()
        call local%unselect_model ()
        call local%unset_values ()
    else if (associated (local%model)) then
        call local%ensure_model_copy ()
    end if
    if (.not. same_model .and. global_model /= "") then
        call msg_message ("Restoring model '" // char (global_model) // "'")
    end if
    if (associated (global%model)) then
        call global%model%link_var_list (global%var_list)
    end if
    call global%restore_globals (local)
else
    call local%unselect_model ()
end if
end subroutine rt_data_deactivate

```

This imports the global objects for which local modifications should be kept. Currently, this is only the process library stack.

```

<RT data: rt data: TBP>+≡
    procedure :: copy_globals => rt_data_copy_globals

<RT data: procedures>+≡
    subroutine rt_data_copy_globals (global, local)
        class(rt_data_t), intent(in) :: global
        class(rt_data_t), intent(inout) :: local
        local%prclib_stack = global%prclib_stack
    end subroutine rt_data_copy_globals

```

This restores global objects, for which local modifications should be kept.

```

<RT data: rt data: TBP>+≡
    procedure :: restore_globals => rt_data_restore_globals

<RT data: procedures>+≡
    subroutine rt_data_restore_globals (global, local)
        class(rt_data_t), intent(inout) :: global
        class(rt_data_t), intent(in) :: local
        global%prclib_stack = local%prclib_stack
    end subroutine rt_data_restore_globals

```

35.2.8 Finalization

Finalizer for the variable list and the structure-function list. This is done only for the global RT dataset; local copies contain pointers to this and do not need

a finalizer.

```

<RT data: rt data: TBP>+≡
  procedure :: final => rt_data_global_final

<RT data: procedures>+≡
  subroutine rt_data_global_final (global)
    class(rt_data_t), intent(inout) :: global
    call global%process_stack%final ()
    call global%prclib_stack%final ()
    ! call global%delete_model_copy ()
    call global%model_list%final ()
    call var_list_final (global%var_list, follow_link=.false.)
    if (associated (global%out_files)) then
      call file_list_final (global%out_files)
      deallocate (global%out_files)
    end if
  end subroutine rt_data_global_final

```

The local copy needs a finalizer for the variable list, which consists of local copies. This finalizer is called only when the local environment is finally discarded. (Note that the process stack should already have been cleared after execution, which can occur many times for the same local environment.)

```

<RT data: rt data: TBP>+≡
  procedure :: local_final => rt_data_local_final

<RT data: procedures>+≡
  subroutine rt_data_local_final (local)
    class(rt_data_t), intent(inout) :: local
    call local%process_stack%clear ()
    ! call local%delete_model_copy ()
    call local%model_list%final ()
    call var_list_final (local%var_list, follow_link=.false.)
  end subroutine rt_data_local_final

```

35.2.9 Model Management

Read a model, so it becomes available for activation. No variables or model copies, this is just initialization.

If this is a local environment, the model will be automatically read into the global context.

```

<RT data: rt data: TBP>+≡
  procedure :: read_model => rt_data_read_model

<RT data: procedures>+≡
  subroutine rt_data_read_model (global, name, model)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name
    type(model_t), pointer, intent(out) :: model
    type(string_t) :: filename
    filename = name // ".mdl"
    call global%model_list%read_model &
      (name, filename, global%os_data, model)

```

```
end subroutine rt_data_read_model
```

Initialize the fallback model. This model is used whenever the current model does not describe all physical particles (hadrons, mainly). It is not supposed to be modified, and the pointer should remain linked to this model.

```
<RT data: rt data: TBP>+≡
  procedure :: init_fallback_model => rt_data_init_fallback_model

<RT data: procedures>+≡
  subroutine rt_data_init_fallback_model (global, name, filename)
    class(rt_data_t), intent(inout) :: global
    type(string_t), intent(in) :: name, filename
    call global%model_list%read_model &
      (name, filename, global%os_data, global%fallback_model)
  end subroutine rt_data_init_fallback_model
```

Activate a model: assign the current-model pointer and set the model name in the variable list. If necessary, read the model from file. Link the global variable list to the model variable list.

```
<RT data: rt data: TBP>+≡
  procedure :: select_model => rt_data_select_model

<RT data: procedures>+≡
  subroutine rt_data_select_model (global, name)
    class(rt_data_t), intent(inout), target :: global
    type(string_t), intent(in) :: name
    logical :: same_model
    if (associated (global%model)) then
      same_model = global%model%get_name () == name
    else
      same_model = .false.
    end if
    if (.not. same_model) then
      ! call global%delete_model_copy ()
      global%model => global%model_list%get_model_ptr (name)
      if (.not. associated (global%model)) then
        call global%read_model (name, global%model)
        global%model_is_copy = .false.
      else if (associated (global%context)) then
        global%model_is_copy = &
          global%model_list%model_exists (name, follow_link=.false.)
      else
        global%model_is_copy = .false.
      end if
    end if
    if (associated (global%model)) then
      call global%model%link_var_list (global%var_list)
      call var_list_set_string (global%var_list, var_str ("$model_name"), &
        name, is_known = .true.)
      call msg_message ("Switching to model '" // char (name) // "'")
    else
      call var_list_set_string (global%var_list, var_str ("model_name"), &
        var_str (""), is_known = .false.)
    end if
```

```

        end if
    end subroutine rt_data_select_model

```

Remove the model link and unset the model name variable.

```

<RT data: rt data: TBP>+≡
    procedure :: unselect_model => rt_data_unselect_model

<RT data: procedures>+≡
    subroutine rt_data_unselect_model (global)
        class(rt_data_t), intent(inout), target :: global
        if (associated (global%model)) then
!            call global%delete_model_copy ()
            global%model => null ()
            global%model_is_copy = .false.
            call var_list_set_string (global%var_list, var_str ("model_name"), &
                var_str (""), is_known = .false.)
        end if
    end subroutine rt_data_unselect_model

```

Create a copy of the currently selected model and append it to the local model list. The model pointer is redirected to the copy. (Not applicable for the global model list, those models will be modified in-place.)

```

<RT data: rt data: TBP>+≡
    procedure :: ensure_model_copy => rt_data_ensure_model_copy
!    procedure :: delete_model_copy => rt_data_delete_model_copy

<RT data: procedures>+≡
    subroutine rt_data_ensure_model_copy (global)
        class(rt_data_t), intent(inout), target :: global
        if (associated (global%context)) then
            if (.not. global%model_is_copy) then

35.2.13 Test

This is the master for calling self-test procedures.

```

<RT data: public>+≡
    public :: rt_data_test

<RT data: tests>≡
    subroutine rt_data_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <RT data: execute tests>
    end subroutine rt_data_test

```

Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

```

<RT data: rt data: TBP>+≡
    procedure :: fix_system_dependencies => rt_data_fix_system_dependencies

```

```

35.3 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

This module provides no new types, just procedures.

```

⟨dispatch.f90⟩≡
  ⟨File header⟩

  module dispatch

end select
end associate
end subroutine dispatch_core_def

```

35.3.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

```
<Dispatch: public>+≡
    public :: dispatch_core

<Dispatch: procedures>+≡
    subroutine dispatch_core (core, core_def, model, &
        helicity_selection, qcd, use_color_factors)
        class(prc_core_t), allocatable, intent(inout) :: core
        class(prc_core_def_t), intent(in) :: core_def
        class(model_data_t), intent(in), target, optional :: model
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        type(qcd_t), intent(in), optional :: qcd
        logical, intent(in), optional :: use_color_factors
        select type (core_def)
            type is (prc_test_def_t)
                allocate (test_t :: core)
            type is (template_me_def_t)
                allocate (prc_template_me_t :: core)
                select type (core)
                    type is (prc_template_me_t)
                        call core%set_parameters (model)
                    end select
            class is (omega_def_t)
                if (.not. allocated (core)) allocate (prc_omega_t :: core)
                select type (core)
                    type is (prc_omega_t)
                        call core%set_parameters (model, &
                            helicity_selection, qcd, use_color_factors)
                    end select
            type is (gosam_def_t)
                if (.not. allocated (core)) allocate (prc_gosam_t :: core)
                select type (core)
                    type is (prc_gosam_t)
                        call core%set_parameters (qcd)
                    end select
            class default
                call msg_bug ("Process core: unexpected process definition type")
                end select
        end subroutine dispatch_core
```

35.3.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

```

<Dispatch: public>+≡
  public :: dispatch_core_update
  public :: dispatch_core_restore

<Dispatch: procedures>+≡
  subroutine dispatch_core_update (core, model, helicity_selection, qcd, &
    saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(model_data_t), intent(in), optional, target :: model
    type(helicity_selection_t), intent(in), optional :: helicity_selection
    type(qcd_t), intent(in), optional :: qcd
    class(prc_core_t), allocatable, intent(inout), optional :: saved_core
    if (present (saved_core)) then
      allocate (saved_core, source = core)
    end if
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
      call core%set_parameters (model, helicity_selection, qcd)
      call core%activate_parameters ()
    type is (prc_gosam_t)
      call msg_message ("dispatch core restore: Gosam implementation not present yet!")
    class default
      call msg_bug ("Process core update: unexpected process definition type")
    end select
  end subroutine dispatch_core_update

  subroutine dispatch_core_restore (core, saved_core)
    class(prc_core_t), allocatable, intent(inout) :: core
    class(prc_core_t), allocatable, intent(inout) :: saved_core
    call move_alloc (from = saved_core, to = core)
    select type (core)
    type is (test_t)
    type is (prc_omega_t)
      call core%activate_parameters ()
    class default
      call msg_bug ("Process core restore: unexpected process definition type")
    end select
  end subroutine dispatch_core_restore

```

35.3.4 Integrator allocation

Allocate an integrator according to the variable \$integration_method.

```

<Dispatch: public>+≡
  public :: dispatch_mci

<Dispatch: procedures>+≡
  subroutine dispatch_mci (mci, global, process_id)
    class(mci_t), allocatable, intent(inout) :: mci
    type(rt_data_t), intent(in) :: global
    type(string_t), intent(in) :: process_id
    type(string_t) :: run_id

```

```

type(string_t) :: integration_method
type(grid_parameters_t) :: grid_par
type(history_parameters_t) :: history_par
logical :: rebuild_grids, check_grid_file, negative_weights, verbose
integration_method = var_list_get_sval (global%var_list, &
    var_str ("integration_method"))
select case (char (integration_method))
case ("midpoint")
    allocate (mci_midpoint_t :: mci)

```

35.3.7 Random-number generator

Allocate a random-number generator factory according to the variable `$rng_method`, using the current seed in the global record. We take only the lower 15 bits of the seed, so the actual value fits into a positive 16-bit signed integer.

Since we want to guarantee that all random-number generators in a run are independent, we increment the global seed by one after creating the rng factory. If the user wants to have identical sequences, he can always set the seed manually, before it is used.

```

<Dispatch: public>+≡
  public :: dispatch_rng_factory

<Dispatch: procedures>+≡
subroutine dispatch_rng_factory (rng_factory, global, local_input)
  class(rng_factory_t), allocatable, intent(inout) :: rng_factory

    call var_list_set_int (global%var_list, var_str ("seed"), seed + 1, &
        is_known = .true.)
end subroutine dispatch_rng_factory

```

35.3.8 Structure function configuration data

This data type is a container for transferring structure-function specific data from the `dispatch_sf_data` to the `dispatch_sf_channels` subroutine.

```

<Dispatch: public>+≡
    public :: sf_prop_t

<Dispatch: types>≡
    type :: sf_prop_t
        real(default), dimension(2) :: isr_eps = 1
    end type sf_prop_t

```

Allocate a structure-function configuration object according to the `sf_method` string.

The `sf_prop` object can be used to transfer structure-function specific data up and to the `dispatch_sf_channels` subroutine below, so they can be used for particular mappings.

The `global` object is intent(inout) because the RNG generator seed may change during initialization.

The `pdg_in` array is the array of incoming flavors, corresponding to the upstream structure function or the beam array. This will be checked for the structure function in question and replaced by the outgoing flavors. The `pdg_prc` array is the array of incoming flavors (beam index, component index) for the hard process.

```

<Dispatch: public>+≡
    public :: dispatch_sf_data

<Dispatch: procedures>+≡
    subroutine dispatch_sf_data (data, sf_method, i_beam, sf_prop, global, &
        pdg_in, pdg_prc)

```

This is an auxiliary procedure, used by the beam-structure expansion: tell for a given structure function name, whether it corresponds to a pair spectrum ($n = 2$), a single-particle structure function ($n = 1$), or nothing ($n = 0$). Though `energy_scan` can in principle also be a pair spectrum, it always has only one parameter.

(Dispatch: procedures)+≡

```

function strfun_mode (name) result (n)
  type(string_t), intent(in) :: name
  integer :: n
  select case (char (name))
  case ("none")
    n = 0

  case default
    call msg_bug ("Structure function '" // char (name) &
                 // "' not supported yet")
  end select
end function strfun_mode

```

Dispatch a whole structure-function chain, given beam data and beam structure data.

This could be done generically, but we should look at the specific combination of structure functions in order to select appropriate mappings.

The `beam_structure` argument gets copied because we want to expand it to canonical form (one valid structure-function entry per record) before proceeding further.

The `pdg_prc` argument is the array of incoming flavors. The first index is the beam index, the second one the process component index. Each element is itself a PDG array, notrivial if there is a flavor sum for the incoming state of this component.

The dispatcher is divided in two parts. The first part configures the structure function data themselves. After this, we can configure the phase space for the

elementary process.

<Dispatch: public>+≡

public :: dispatch_sf_config

<Dispatch: procedures>+≡

```

subroutine dispatch_sf_config (sf_config, sf_prop, global, pdg_prc)
  type(sf_config_t), dimension(:), allocatable, intent(out) :: sf_config
  type(sf_prop_t), intent(out) :: sf_prop
  type(rt_data_t), intent(inout) :: global
  type(beam_structure_t) :: beam_structure
  class(sf_data_t), allocatable :: sf_data
  type(pdg_array_t), dimension(:,:), intent(in) :: pdg_prc
  type(string_t), dimension(:), allocatable :: prt_in
  type(pdg_array_t), dimension(:), allocatable :: pdg_in
  type(flavor_t) :: flv_in
  integer :: n_beam, n_record, i
  beam_structure = global%beam_structure
  call beam_structure%expand (strfun_mode)
  n_record = beam_structure%get_n_record ()
  allocate (sf_config (n_record))
  n_beam = beam_structure%get_n_beam ()
  if (n_beam > 0) then
    allocate (prt_in (n_beam), pdg_in (n_beam))
    prt_in = beam_structure%get_prt ()
    do i = 1, n_beam
      call flavor_init (flv_in, prt_in(i), global%model)
      pdg_in(i) = flavor_get_pdg (flv_in)
    end do
  else
    n_beam = size (pdg_prc, 1)
    allocate (pdg_in (n_beam))
    pdg_in = pdg_prc(:,1)
  end if
  do i = 1, n_record
    call dispatch_sf_data (sf_data, &
      beam_structure%get_name (i), &
      beam_structure%get_i_entry (i), &
      sf_prop, global, pdg_in, pdg_prc)
    call sf_config(i)%init (beam_structure%get_i_entry (i), sf_data)
    deallocate (sf_data)
  end do
end subroutine dispatch_sf_config

```

The second part configures channel mappings, using some conditions from the phase space configuration. If there are no structure functions, we enable a default setup with a single (dummy) structure-function channel. Otherwise, we look at the channel collection that we got from the phase-space configuration step. Each entry should be translated into an independent structure-function channel, where typically there is one default entry, which could be mapped using a standard s-channel mapping if the structure function setup recommends this, and other entries with s-channel resonances. The latter need to be translated into global mappings from the structure-function chain.

```

35.3.10 QCD coupling

Allocate the `alpha` (running coupling) component of the `qcd` block with a concrete implementation, depending on the variable settings in the `global` record.

If a fixed α_s is requested, we do not allocate the `qcd%alpha` object. In this case, the matrix element code will just take the model parameter as-is, which implies fixed α_s . If the object is allocated, the α_s value is computed and updated for each matrix-element call.

```

35.4 Process Configuration

This module communicates between the toplevel command structure with its runtime data set and the process-library handling modules which collect the definition of individual processes. Its primary purpose is to select from the available matrix-element generating methods and configure the entry in the process library accordingly.

```

<process_configurations.f90>≡
  <File header>

  module process_configurations

    <Use strings>
    use unit_tests
    use diagnostics

    use variables
    use models
    use prc_core_def
    use particle_specifiers
    use process_libraries
    use prclib_stacks
    use prc_test
    use prc_omega
    use rt_data
    use dispatch

    use prc_gosam

    <Standard module head>

    <Process configurations: public>

    <Process configurations: types>

    contains

    <Process configurations: procedures>

    <Process configurations: tests>

  end module process_configurations

```

35.4.1 Data Type

```

<Process configurations: public>≡
  public :: process_configuration_t

<Process configurations: types>≡
  type :: process_configuration_t
    type(process_def_entry_t), pointer :: entry => null ()
    type(string_t) :: id
    integer :: num_id = 0
  contains
    <Process configurations: process configuration: TBP>
  end type process_configuration_t

```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

```

<Process configurations: process configuration: TBP>≡
  procedure :: init => process_configuration_init

```

```

<Process configurations: procedures>≡
  subroutine process_configuration_init &
    (config, prc_name, n_in, n_components, global)
    class(process_configuration_t), intent(out) :: config
    type(string_t), intent(in) :: prc_name
    integer, intent(in) :: n_in
    integer, intent(in) :: n_components

    end if
  end subroutine process_configuration_init

```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

```

```

35.4.2 Test

This is the master for calling self-test procedures.

```

<Process configurations: public>+≡
    public :: process_configurations_test

<Process configurations: tests>≡
    subroutine process_configurations_test (u, results)
        integer, intent(in) :: u
        type(test_results_t), intent(inout) :: results
    <Process configurations: execute tests>
    end subroutine process_configurations_test

```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined `procname(s)`.

```

<Process configurations: public>+≡
    public :: prepare_test_library

<Process configurations: tests>+≡
    subroutine prepare_test_library (global, libname, mode, procname)

35.5 Compilation

This module manages compilation and loading of process libraries. It is needed as a separate module because integration depends on it.

```

<compilations.f90>≡
  <File header>

  module compilations

    <Use strings>
    use io_units
    use unit_tests
    use system_defs, only: TAB
    use diagnostics
    use os_interface
    use md5
    use variables
    use model_data
    use models
    use process_libraries
    use prclib_stacks
    use rt_data
    use process_configurations

    <Standard module head>

    <Compilations: public>

    <Compilations: types>

    contains

    <Compilations: procedures>

    <Compilations: tests>

  end module compilations

```

35.5.1 The data type

The compilation item handles the compilation and loading of a single process library.

```

<Compilations: types>≡
  type :: compilation_item_t

```

```

    type(string_t) :: libname
    type(process_library_t), pointer :: lib => null ()
    logical :: recompile_library = .false.
contains
  <Compilations: compilation item: TBP>
end type compilation_item_t

```

Initialize:

```

<Compilations: compilation item: TBP>≡
  procedure :: init => compilation_item_init

<Compilations: procedures>≡
  subroutine compilation_item_init (comp, libname, stack, var_list)
    class(compilation_item_t), intent(out) :: comp
    type(string_t), intent(in) :: libname
    type(prclib_stack_t), intent(inout) :: stack
    type(var_list_t), intent(in) :: var_list
    comp%libname = libname
    comp%lib => stack%get_library_ptr (comp%libname)
    if (.not. associated (comp%lib)) then
      call msg_fatal ("Process library '" // char (comp%libname) &
        // "' has not been declared.")
    end if
    comp%recompile_library = &
      var_list_get_lval (var_list, var_str ("?recompile_library"))
  end subroutine compilation_item_init

```

Compile the current library. The force flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

```

<Compilations: compilation item: TBP>+≡
  procedure :: compile => compilation_item_compile

<Compilations: procedures>+≡
  subroutine compilation_item_compile (comp, model, os_data, force, recompile)
    class(compilation_item_t), intent(inout) :: comp
    class(model_data_t), intent(in), target :: model
    type(os_data_t), intent(in) :: os_data
    logical, intent(in) :: force, recompile
    if (associated (comp%lib)) then
      call msg_message ("Process library '" &
        // char (comp%libname) // "': compiling ...")
      call comp%lib%configure (os_data)
      if (signal_is_pending ()) return
      call comp%lib%compute_md5sum (model)
      call comp%lib%write_makefile (os_data, force)
      if (signal_is_pending ()) return
      if (force) then
        call comp%lib%clean (os_data, distclean = .false.)
        if (signal_is_pending ()) return
      end if
      call comp%lib%write_driver (force)
      if (signal_is_pending ()) return
      if (recompile) then

```

```

        call comp%lib%load (os_data, keep_old_source = .true.)
        if (signal_is_pending ()) return
    end if
    call comp%lib%update_status (os_data)
end if
end subroutine compilation_item_compile

```

Load the current library, just after compiling it.

```

<Compilations: compilation item: TBP>+≡
    procedure :: load => compilation_item_load

<Compilations: procedures>+≡
    subroutine compilation_item_load (comp, os_data)
        class(compilation_item_t), intent(inout) :: comp
        type(os_data_t), intent(in) :: os_data
        if (associated (comp%lib)) then
            call comp%lib%load (os_data)
        end if
    end subroutine compilation_item_load

```

Message as a separate call:

```

<Compilations: compilation item: TBP>+≡
    procedure :: success => compilation_item_success

<Compilations: procedures>+≡
    subroutine compilation_item_success (comp)
        class(compilation_item_t), intent(in) :: comp
        if (associated (comp%lib)) then
            call msg_message ("Process library '" // char (comp%libname) &
                // "' : ... success.")
        else
            call msg_fatal ("Process library '" // char (comp%libname) &
                // "' : ... failure.")
        end if
    end subroutine compilation_item_success

```

35.5.2 API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>≡
    public :: compile_library

<Compilations: procedures>+≡
    subroutine compile_library (libname, global)
        type(string_t), intent(in) :: libname
        type(rt_data_t), intent(inout), target :: global
        type(compilation_item_t) :: comp
        logical :: force, recompile

```

```

force = &
    var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
recompile = &
    var_list_get_lval (global%var_list, var_str ("?recompile_library"))
if (associated (global%model)) then
    call comp%init (libname, global%prclib_stack, global%var_list)
    call comp%compile (global%model, global%os_data, force, recompile)
    if (signal_is_pending ()) return
    call comp%load (global%os_data)
    if (signal_is_pending ()) return
else
    call msg_fatal ("Process library compilation: " &
        // " model is undefined.")
end if
call comp%success ()
end subroutine compile_library

```

35.5.3 Compiling static executable

This object handles the creation of a static executable which should contain a set of static process libraries.

```

<Compilations: types>+≡
type :: compilation_t
private
    type(string_t) :: exe_name
    type(string_t), dimension(:), allocatable :: lib_name
contains
    <Compilations: compilation: TBP>
end type compilation_t

```

Output.

```

<Compilations: compilation: TBP>≡
procedure :: write => compilation_write

<Compilations: procedures>+≡
subroutine compilation_write (object, unit)
class(compilation_t), intent(in) :: object
integer, intent(in), optional :: unit
integer :: u, i
u = given_output_unit (unit)
write (u, "(1x,A)") "Compilation object:"
write (u, "(3x,3A)") "executable      = '", &
    char (object%exe_name), "'"
write (u, "(3x,A)", advance="no") "process libraries ="
do i = 1, size (object%lib_name)
    write (u, "(1x,3A)", advance="no") "'", char (object%lib_name(i)), "'"
end do
write (u, *)
end subroutine compilation_write

```

Initialize: we know the names of the executable and of the libraries.

```

<Compilations: compilation: TBP>+≡
  procedure :: init => compilation_init

<Compilations: procedures>+≡
  subroutine compilation_init (compilation, exe_name, lib_name)
    class(compilation_t), intent(out) :: compilation
    type(string_t), intent(in) :: exe_name
    type(string_t), dimension(:), intent(in) :: lib_name
    compilation%exe_name = exe_name
    allocate (compilation%lib_name (size (lib_name)))
    compilation%lib_name = lib_name
  end subroutine compilation_init

```

Write the dispatcher subroutine for the compiled libraries. Also write a subroutine which returns the names of the compiled libraries.

```

<Compilations: compilation: TBP>+≡

            // " -f " // compilation%exe_name // ".makefile")
    end subroutine compilation_make_clean_exe

```

35.5.4 API for executable compilation

This is a shorthand for compiling and loading an executable, including the enclosed libraries. The `compilation` object is used only internally.

The `global` data set may actually be local to the caller. The compilation affects the library specified by its name if it is on the stack, but it does not reset the currently selected library.

```

<Compilations: public>+≡
    public :: compile_executable

```

```

<Compilations: procedures>+≡
  subroutine compile_executable (exename, libname, global)
    type(string_t), intent(in) :: exename
    type(string_t), dimension(:), intent(in) :: libname
    type(rt_data_t), intent(inout), target :: global
    type(compilation_t) :: compilation
    type(compilation_item_t) :: item
    logical :: force, recompile
    integer :: i
    force = &
      var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
    recompile = &
      var_list_get_lval (global%var_list, var_str ("?recompile_library"))
    call compilation%init (exename, [libname])
    if (signal_is_pending ()) return
    call compilation%write_dispatcher ()
    if (signal_is_pending ()) return
    call compilation%write_makefile (global%os_data)
    if (signal_is_pending ()) return
    do i = 1, size (libname)
      call item%init (libname(i), global%prclib_stack, global%var_list)
      call item%compile (global%model, global%os_data, &
        force=force, recompile=recompile)
      if (signal_is_pending ()) return
      call item%success ()
    end do
    call compilation%make_compile (global%os_data)
    if (signal_is_pending ()) return
    call compilation%make_link (global%os_data)
  end subroutine compile_executable

```

35.5.5 Test

This is the master for calling self-test procedures.

```

<Compilations: public>+≡
  public :: compilations_test

<Compilations: tests>≡
  subroutine compilations_test (u, results)
    integer, intent(in) :: u
    type(test_results_t), intent(inout) :: results
    <Compilations: execute tests>
  end subroutine compilations_test

```

Intrinsic Matrix Element

Compile an intrinsic test matrix element (prc_test type).

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```

<Compilations: execute tests>≡
  call test (compilations_1, "compilations_1", &

```

```

        "intrinsic test processes", &
        u, results)
<Compilations: tests>+≡
subroutine compilations_1 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname
    type(rt_data_t), target :: global

    write (u, "(A)")  "* Test output: compilations_1"
    write (u, "(A)")  "*   Purpose: configure and compile test process"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()

    libname = "compilation_1"
    procname = "prc_comp_1"
    call prepare_test_library (global, libname, 1, [procname])

    call compile_library (libname, global)

```

```
end subroutine compilations_static_1
```

External Matrix Element

Compile an external test matrix element (*omega* type) and incorporate this in a new static WHIZARD executable. In this version, we use the wrapper `compile_executable` procedure.

```
(Compilations: static tests)+≡
  call test (compilations_static_2, "compilations_static_2", &
    "static executable: shortcut", &
    u, results)

(Compilations: tests)+≡
  subroutine compilations_static_2 (u)
    integer, intent(in) :: u
    type(string_t) :: libname, procname, exename
    type(rt_data_t), target :: global
    type(compilation_item_t) :: item
    type(compilation_t) :: compilation
    logical :: exist
    integer :: u_file

    write (u, "(A)")  "* Test output: compilations_static_2"
    write (u, "(A)")  "* Purpose: make static executable"
    write (u, "(A)")

    write (u, "(A)")  "* Initialize library and compile"
    write (u, "(A)")

    call syntax_model_file_init ()

    call global%global_init ()
    call var_list_set_log (global%var_list, var_str ("?omega_omp"), &
      .false., is_known = .true.)

    libname = "compilations_static_2_lib"
    procname = "prc_comp_stat_2"
    exename = "compilations_static_2"

    call prepare_test_library (global, libname, 2, [procname,procname])

    call compile_executable (exename, [libname], global)

    write (u, "(A)")  "* Check executable (should be present)"
    write (u, "(A)")

    inquire (file = char (exename), exist = exist)
    write (u, "(A,A,L1)") char (exename), " exists = ", exist

    write (u, "(A)")
    write (u, "(A)")  "* Cleanup"
```

```

u_file = free_unit ()
open (u_file, file = char (exename), status = "old", action = "write")
close (u_file, status = "delete")

call global%final ()
call syntax_model_file_final ()

write (u, "(A)")
write (u, "(A)")  "*" Test output end: compilations_static_2"

end subroutine compilations_static_2

```

35.6 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

`<integrations.f90>`≡

<Integrations: procedures>

<Integrations: tests>

end module integrations

```

35.6.1 The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

```

<Integrations: public>≡
    public :: integration_t

<Integrations: types>≡
    type :: integration_t
    private
        type(string_t) :: process_id
        type(string_t) :: run_id
        type(process_t), pointer :: process => null ()
        type(var_list_t), pointer :: model_vars => null ()
        type(qcd_t) :: qcd
        logical :: rebuild_phs = .false.
        logical :: ignore_phs_mismatch = .false.
        logical :: phs_only = .false.
        logical :: process_has_me = .true.
        integer :: n_calls_test = 0
        logical :: vis_history = .true.
        type(string_t) :: history_filename
        type(string_t) :: log_filename
    contains
    <Integrations: integration: TBP>

```

```
end type integration_t
```

35.6.2 Initialization

Initialization, first part: Create a process entry. Push it on the stack if the global environment is supplied.

(Integrations: integration: TBP)≡

```
procedure :: create_process => integration_create_process
```

(Integrations: procedures)≡

```
subroutine integration_create_process (intg, process_id, global)
  class(integration_t), intent(out) :: intg
  type(rt_data_t), intent(inout), optional, target :: global
  type(string_t), intent(in) :: process_id
  type(process_entry_t), pointer :: process_entry
  intg%process_id = process_id
  if (present (global)) then
    allocate (process_entry)
    intg%process => process_entry%process_t
    call global%process_stack%push (process_entry)
  else
    allocate (process_t :: intg%process)
  end if
  intg%model_vars => null ()
end subroutine integration_create_process
```

Initialization, second part: Initialize the process object, using the local environment. We allocate a RNG factory and a QCD object. We also fetch a pointer to the model that the process uses. The process initializer will create a snapshot of that model.

This procedure does not modify the local stack directly. The intent(inout) attribute for the local data set is due to the random generator seed which may be incremented during initialization.

NOTE: Changes to model parameters within the current context are respected only if the process model coincides with the current model. This is the usual case. If not, we read the model from the global model library, which has default parameters. To become more flexible, we should implement a local model library which records local changes to currently inactive models.

(Integrations: integration: TBP)+≡

```
procedure :: init_process => integration_init_process
```

(Integrations: procedures)+≡

```
subroutine integration_init_process (intg, local)
  class(integration_t), intent(inout) :: intg
  type(rt_data_t), intent(inout), target :: local
  type(string_t) :: model_name
  type(model_t), pointer :: model
  class(model_data_t), pointer :: model_instance
  class(rng_factory_t), allocatable :: rng_factory
  intg%run_id = var_list_get_sval (local%var_list, var_str ("$_run_id"))
  call dispatch_qcd (intg%qcd, local)
```

```

call dispatch_rng_factory (rng_factory, local)
model_name = local%prclib%get_model_name (intg%process_id)
if (local%get_sval (var_str ("model_name")) == model_name) then
    model => local%model
else
    model => local%model_list%get_model_ptr (model_name)
end if
allocate (model_t :: model_instance)
select type (model_instance)
type is (model_t)
    call model_instance%init_instance (model)
    intg%model_vars => model_instance%get_var_list_ptr ()
end select
call intg%process%init (intg%process_id, intg%run_id, &
    local%prclib, &
    local%os_data, intg%qcd, rng_factory, model_instance)
end subroutine integration_init_process

```

Initialization, third part: complete process configuration.

(Integrations: integration: TBP)+≡

```

procedure :: setup_process => integration_setup_process

```

(Integrations: procedures)+≡

```

35.6.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

```

(Integrations: integration: TBP)+≡
  procedure :: evaluate => integration_evaluate

(Integrations: procedures)+≡
  subroutine integration_evaluate &
    (intg, process_instance, i_mci, pass, it_list, pacify)
    class(integration_t), intent(inout) :: intg
    type(process_instance_t), intent(inout), target :: process_instance
    integer, intent(in) :: i_mci
    integer, intent(in) :: pass
    type(iterations_list_t), intent(in) :: it_list
    logical, intent(in), optional :: pacify
    integer :: n_calls, n_it
    logical :: adapt_grids, adapt_weights, final

    n_it = it_list%get_n_it (pass)
    n_calls = it_list%get_n_calls (pass)
    adapt_grids = it_list%adapt_grids (pass)
    adapt_weights = it_list%adapt_weights (pass)
    final = pass == it_list%get_n_pass ()

    call intg%process%integrate (process_instance, &
      i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
      final, pacify)

  end subroutine integration_evaluate

```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

```

(Integrations: integration: TBP)+≡
  procedure :: make_iterations_list => integration_make_iterations_list

(Integrations: procedures)+≡
  subroutine integration_make_iterations_list (intg, it_list)

end subroutine integration_sampler_test

```

Return the process pointer (needed by simulate):

```

<Integrations: integration: TBP>+≡
    procedure :: get_process_ptr => integration_get_process_ptr

<Integrations: procedures>+≡
    function integration_get_process_ptr (intg) result (ptr)
        class(integration_t), intent(in) :: intg
        type(process_t), pointer :: ptr
        ptr => intg%process
    end function integration_get_process_ptr

```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

If the global environment is provided, the process object is appended to the global stack. Otherwise, if `local_stack` is set, we append to the local process stack. If this is unset, the process object is not recorded permanently.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

```

Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \quad (35.1)$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \quad (35.2)$$

f is the flux of the incoming particles with mass $m = 125 \text{ GeV}$ and energy $\sqrt{s} = 1000 \text{ GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\sqrt{s-4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \quad (35.3)$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \quad (35.4)$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \quad (35.5)$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

```

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using the default (`phs_wood`) phase-space implementation. The integration method is `vamp`. There is a structure function of type `unit_test`.

We use a test structure function $f(x) = x$ for both beams. Together with the $1/x_1x_2$ factor from the phase-space flux and a unit matrix element, we should get the same result as previously for the process without structure functions. There is a slight correction due to the m_s mass which we set to zero here.

```

35.7 Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

```

(event_streams.f90)≡
  <File header>

  module event_streams

    <Use kinds>
    <Use strings>
    use io_units
    use unit_tests
    use diagnostics
    use variables
    use model_data
    use models
    use processes
    use events
    use eio_data
    use eio_base
    use rt_data
    use dispatch

    <Standard module head>

    <Event streams: public>

    <Event streams: types>

    contains

    <Event streams: tests>

    <Event streams: procedures>

  end module event_streams

```

35.7.1 Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

```
<Event streams: types>≡  
  type :: event_stream_entry_t  
    class(eio_t), allocatable :: eio  
  end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

```
<Event streams: public>≡  
  public :: event_stream_array_t  
  
<Event streams: types>+≡  
  type :: event_stream_array_t  
    type(event_stream_entry_t), dimension(:), allocatable :: entry  
    integer :: i_in = 0  
  contains  
    <Event streams: event stream array: TBP>  
  end type event_stream_array_t
```

Output.

```
<Event streams: event stream array: TBP>≡  
  procedure :: write => event_stream_array_write  
  
<Event streams: procedures>≡  
  subroutine event_stream_array_write (object, unit)  
    class(event_stream_array_t), intent(in) :: object  
    integer, intent(in), optional :: unit  
    integer :: u, i  
    u = given_output_unit (unit)  
    write (u, "(1x,A)") "Event stream array:"  
    if (allocated (object%entry)) then  
      select case (size (object%entry))  
      case (0)  
        write (u, "(3x,A)") "[empty]"  
      case default  
        do i = 1, size (object%entry)  
          if (i == object%i_in) write (u, "(1x,A)") "Input stream:"  
          call object%entry(i)%eio%write (u)  
        end do  
      end select  
    else  
      write (u, "(3x,A)") "[undefined]"  
    end if  
  end subroutine event_stream_array_write
```

Finalize all streams.

```
<Event streams: event stream array: TBP>+≡  
  procedure :: final => event_stream_array_final
```

```

(Event streams: procedures)+≡
subroutine event_stream_array_final (es_array)
  class(event_stream_array_t), intent(inout) :: es_array
  integer :: i
  do i = 1, size (es_array%entry)
    call es_array%entry(i)%eio%final ()
  end do
end subroutine event_stream_array_final

```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

```

  end if
end subroutine mci_set_init

```

35.8.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

(Simulations: types)+≡

```

type :: core_safe_t
  class(prc_core_t), allocatable :: core
end type core_safe_t

```

35.8.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration is not yet done, do it. Any generated process object should be put on the global stack, if it is separate from the local one.

(Simulations: procedures)+≡

```
subroutine prepare_process &
  (process, process_id, integrate, local, global)
  type(process_t), pointer, intent(out) :: process
  type(string_t), intent(in) :: process_id
  logical, intent(in) :: integrate
  type(rt_data_t), intent(inout), target :: local
  type(rt_data_t), intent(inout), optional, target :: global
  if (present (global)) then
    process => global%process_stack%get_process_ptr (process_id)
  else
    process => local%process_stack%get_process_ptr (process_id)
  end if
  if (.not. associated (process)) then
    if (integrate) then
      call msg_message ("Simulate: process '" &
        // char (process_id) // "' needs integration")
    else
      call msg_message ("Simulate: process '" &
        // char (process_id) // "' needs initialization")
    end if
    if (present (global)) then
      call integrate_process (process_id, local, global, &
        init_only = .not. integrate)
    else
      call integrate_process (process_id, local, local_stack=.true., &
        init_only = .not. integrate)
    end if
    if (signal_is_pending ()) return
    process => global%process_stack%get_process_ptr (process_id)
    if (associated (process)) then
      if (integrate) then
        call msg_message ("Simulate: integration done")
        call global%process_stack%fill_result_vars (process_id)
      else
        call msg_message ("Simulate: process initialization done")
      end if
    else
      call msg_fatal ("Simulate: process '" &
        // char (process_id) // "' could not be initialized: aborting")
    end if
  end if
end subroutine prepare_process
```

35.8.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

```

<Simulations: types>+≡
  type, extends (event_t) :: entry_t
  private
    type(string_t) :: process_id
    type(string_t) :: library
    type(string_t) :: run_id
    logical :: has_integral = .false.
    real(default) :: integral = 0
    real(default) :: error = 0
    real(default) :: process_weight = 0
    logical :: valid = .false.
    type(counter_t) :: counter
    integer :: n_in = 0
    integer :: n_mci = 0
    type(mci_set_t), dimension(:), allocatable :: mci_set
    type(selector_t) :: mci_selector
    type(core_safe_t), dimension(:), allocatable :: core_safe
    class(model_data_t), pointer :: model => null ()
    type(qcd_t) :: qcd
    logical :: nlo_event = .false.
  contains
    <Simulations: entry: TBP>
  end type entry_t

```

Output. Write just the configuration, the event is written by a separate routine.

The `verbose` option is unused, it is required by the interface of the base-object method.

```

<Simulations: entry: TBP>≡
  procedure :: write_config => entry_write_config

<Simulations: procedures>+≡
  subroutine entry_write_config (object, unit)
    class(entry_t), intent(in) :: object
    integer, intent(in), optional :: unit
    integer :: u, i
    u = given_output_unit (unit)
    write (u, "(3x,A,A,A)") "Process   = '", char (object%process_id), "'"
    write (u, "(3x,A,A,A)") "Library   = '", char (object%library), "'"

```

```

write (u, "(3x,A,A,A)") "Run      = '", char (object%run_id), "'
write (u, "(3x,A,L1)")  "is valid = ", object%valid
if (object%has_integral) then
  write (u, "(3x,A," // FMT_19 // ")") "Integral = ", object%integral
  write (u, "(3x,A," // FMT_19 // ")") "Error    = ", object%error
  write (u, "(3x,A,F13.10)") "Weight   =", object%process_weight
else
  write (u, "(3x,A)") "Integral = [undefined]"
end if
write (u, "(3x,A,I0)") "MCI sets = ", object%n_mci
call object%counter%write (u)
do i = 1, size (object%mci_set)
  write (u, "(A)")
  write (u, "(1x,A,I0,A)") "MCI set #", i, ":"
  call object%mci_set(i)%write (u)
end do
if (allocated (object%core_safe)) then
  do i = 1, size (object%core_safe)
    write (u, "(1x,A,I0,A)") "Saved process-component core #", i, ":"
    call object%core_safe(i)%core%write (u)
  end do
end if
end subroutine entry_write_config

```

Finalizer. The `instance` pointer component of the `event_t` base type points to a target which we did explicitly allocate in the `entry_init` procedure. Therefore, we finalize and explicitly deallocate it here. Then we call the finalizer of the base type.

```

<Simulations: entry: TBP>+≡
  procedure :: final => entry_final

<Simulations: procedures>+≡
  subroutine entry_final (object)
    class(entry_t), intent(inout) :: object
    integer :: i
    if (associated (object%instance)) then
      do i = 1, object%n_mci
        call object%instance%final_simulation (i)
      end do
      call object%instance%final ()
      deallocate (object%instance)
    end if
    call object%event_t%final ()
  end subroutine entry_final

```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the `process_instance` pointer. Assign data by looking at the process object and at the environment.

If `n_alt` is set, we prepare for additional alternate sqme and weight entries.

If the process object is not found initially: if `integrate` is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If `generate` is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the `instance` and `process` pointers of the base type by the `connect` method, so we can reference them later.

```

<Simulations: entry: TBP>+≡

35.8.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

```

<Simulations: types>+≡
    type, extends (entry_t) :: alt_entry_t
    contains
    <Simulations: alt entry: TBP>
end type alt_entry_t

```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

```

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If **integrate** is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If **integrate** is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If **generate** is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take

`n_events` at face value as the number of matrix element calls. For unweighted events, if the process is a decay, `n_events` is the number of unweighted events. In these cases, the luminosity setting is ignored.

For unweighted events with a scattering process, we calculate the event number that corresponds to the luminosity, given the current value of the integral. We then compare this with `n_events` and choose the larger number.

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element “object” is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

These routines take care of temporary parameter redefinitions that we want to take effect while recalculating the matrix elements. We extract the core(s) of the processes that we are simulating, apply the changes, and make sure that the changes are actually used. This is the duty of `dispatch_core_update`. When done, we restore the original versions using `dispatch_core_restore`.

```

<Simulations: simulation: TBP>+=
    procedure :: update_processes => simulation_update_processes
    procedure :: restore_processes => simulation_restore_processes

<Simulations: procedures>+=
    subroutine simulation_update_processes (simulation, &
        model, qcd, helicity_selection)
        class(simulation_t), intent(inout) :: simulation
        class(model_data_t), intent(in), optional, target :: model
        type(qcd_t), intent(in), optional :: qcd
        type(helicity_selection_t), intent(in), optional :: helicity_selection
        integer :: i
        do i = 1, simulation%n_prc
            call simulation%entry(i)%update_process (model, qcd, helicity_selection)
        end do
    end subroutine simulation_update_processes

    subroutine simulation_restore_processes (simulation)
        class(simulation_t), intent(inout) :: simulation
        integer :: i
        do i = 1, simulation%n_prc
            call simulation%entry(i)%restore_process ()
        end do
    end subroutine simulation_restore_processes

```

35.8.8 Event Stream I/O

Write an event to a generic `eio` event stream. The process index must be selected, or the current index must be available.

```

<Simulations: simulation: TBP>+=
    generic :: write_event => write_event_eio
    procedure :: write_event_eio => simulation_write_event_eio

<Simulations: procedures>+=
    subroutine simulation_write_event_eio (object, eio, i_prc)
        class(simulation_t), intent(in) :: object
        class(eio_t), intent(inout) :: eio
        integer, intent(in), optional :: i_prc
        integer :: current
        if (present (i_prc)) then

```

```

        current = i_prc
    else
        current = object%i_prc
    end if
    if (current > 0) then
        if (object%split_n_evt > 0) then
            if (object%counter%total > 1 .and. &
                mod (object%counter%total, object%split_n_evt) == 1) then
                call eio%split_out ()
            end if
        end if
        call eio%output (object%entry(current)%event_t, current)
    else
        call msg_fatal ("Simulation: write event: no process selected")
    end if
end subroutine simulation_write_event_eio

```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

```

<Simulations: simulation: TBP>+=
    generic :: read_event => read_event_eio
    procedure :: read_event_eio => simulation_read_event_eio

<Simulations: procedures>+=
    subroutine simulation_read_event_eio (object, eio)
        class(simulation_t), intent(inout) :: object
        class(eio_t), intent(inout) :: eio
        integer :: iostat, current
        call eio%input_i_prc (current, iostat)
        select case (iostat)
        case (0)
            object%i_prc = current
            call eio%input_event (object%entry(current)%event_t, iostat)
        end select
        select case (iostat)
        case (:-1)
            object%i_prc = 0
            object%i_mci = 0
        case (1:)
            call msg_error ("Reading events: I/O error, aborting read")
            object%i_prc = 0
            object%i_mci = 0
        case default
            object%i_mci = object%entry(current)%get_i_mci ()
        end select
    end subroutine simulation_read_event_eio

```

35.8.9 Event Stream Array

Write an event using an array of event I/O streams. The process index must be selected, or the current index must be available.

```
<Simulations: simulation: TBP>+=  
    generic :: write_event => write_event_es_array  
    procedure :: write_event_es_array => simulation_write_event_es_array  
  
<Simulations: procedures>+=  
    subroutine simulation_write_event_es_array (object, es_array)  
        class(simulation_t), intent(in) :: object  
        class(event_stream_array_t), intent(inout) :: es_array  
        integer :: i_prc, event_index  
        i_prc = object%i_prc  
        if (i_prc > 0) then  
            event_index = object%counter%total  
            call es_array%output (object%entry(i_prc)%event_t, i_prc, event_index)  
        else  
            call msg_fatal ("Simulation: write event: no process selected")  
        end if  
    end subroutine simulation_write_event_es_array
```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

```
<Simulations: simulation: TBP>+=  
    generic :: read_event => read_event_es_array  
    procedure :: read_event_es_array => simulation_read_event_es_array  
  
<Simulations: procedures>+=  
    subroutine simulation_read_event_es_array (object, es_array, enable_switch, &  
        fail)  
        class(simulation_t), intent(inout) :: object  
        class(event_stream_array_t), intent(inout) :: es_array  
        logical, intent(in) :: enable_switch  
        logical, intent(out) :: fail  
        integer :: iostat, i_prc  
        if (es_array%has_input ()) then  
            fail = .false.  
            call es_array%input_i_prc (i_prc, iostat)  
            select case (iostat)  
            case (0)  
                object%i_prc = i_prc  
                call es_array%input_event (object%entry(i_prc)%event_t, iostat)  
            case (:-1)  
                write (msg_buffer, "(A,1x,I0,1x,A)") &  
                    "... event file terminates after", &  
                    object%counter%read, "events."  
                call msg_message ()  
                if (enable_switch) then  
                    call es_array%switch_inout ()  
                    write (msg_buffer, "(A,1x,I0,1x,A)") &
```

```

        "Generating remaining ", &
        object%n_evt_requested - object%counter%read, "events ..."
    call msg_message ()
end if
fail = .true.

end select
else
    fail = .true.
end if
end subroutine simulation_read_event_es_array

```

35.8.10 Recover event

Recalculate the process instance contents, given an event with known particle set. The indices for MC, term, and channel must be already set. The `recalculate` method of the selected entry will import the result into `sqme_prc` and `weight_prc`.

```

<Simulations: simulation: TBP>+≡
    procedure :: recalculate => simulation_recalculate

<Simulations: procedures>+≡
    subroutine simulation_recalculate (simulation, update_sqme, update_weight, &
        recover_beams)
        class(simulation_t), intent(inout) :: simulation
        logical, intent(in) :: update_sqme, update_weight
        logical, intent(in), optional :: recover_beams
        integer :: i_prc
        i_prc = simulation%i_prc
        associate (entry => simulation%entry(i_prc))
            if (update_weight) then
                call simulation%entry(i_prc)%recalculate &
                    (update_sqme = update_sqme, recover_beams = recover_beams, &
                     weight_factor = entry%get_kinematical_weight ())
            else
                call simulation%entry(i_prc)%recalculate &
                    (update_sqme = update_sqme, recover_beams = recover_beams)
            end if
        end associate
    end subroutine simulation_recalculate

```

35.8.11 Extract contents

Return an array of pointers to the currently selected processes.

```
<Simulations: simulation: TBP>+≡  
  procedure :: get_process_ptr => simulation_get_process_ptr  
  
<Simulations: procedures>+≡  
  function simulation_get_process_ptr (simulation) result (ptr)  
    class(simulation_t), intent(in) :: simulation  
    type(process_ptr_t), dimension(:), allocatable :: ptr  
    integer :: i  
    allocate (ptr (simulation%n_prc))  
    do i = 1, size (ptr)  
      ptr(i)%ptr => simulation%entry(i)%get_process_ptr ()  
    end do  
  end function simulation_get_process_ptr
```

Return the MD5 sum that summarizes configuration and integration (but not the event file). Used for initializing the event streams.

```
<Simulations: simulation: TBP>+≡  
  procedure :: get_md5sum_prc => simulation_get_md5sum_prc  
  procedure :: get_md5sum_cfg => simulation_get_md5sum_cfg

Chapter 36

More Unit Tests

36.1 Expression Testing

Expression objects are part of process and event objects, but the process and event object modules should not depend on the implementation of expressions. Here, we collect unit tests that depend on expression implementation.

```
<expr_tests.f90>≡  
  <File header>  
  module expr_tests  
  
    <Use kinds>  
    <Use strings>  
    use format_defs, only: FMT_12  
    use format_utils, only: write_separator  
    use unit_tests  
    use os_interface  
    use ifiles  
    use lexers  
    use parser  
    use lorentz  
    use sm_qcd  
    use model_data  
    use interactions, only: reset_interaction_counter  
    use variables  
    use expr_base  
    use eval_trees  
    use models  
    use subevents  
    use subevt_expr  
    use phs_base  
    use rng_base  
    use mci_base  
    use process_libraries  
    use prc_test  
    use prc_core  
    use processes  
    use events
```

37.1.1 The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

```

⟨Commands: types⟩≡
type, abstract :: command_t
  type(parse_node_t), pointer :: pn => null ()
  class(command_t), pointer :: next => null ()
  type(parse_node_t), pointer :: pn_opt => null ()
  type(command_list_t), pointer :: options => null ()
  type(rt_data_t), pointer :: local => null ()
contains

```

```

    <Commands: command: TBP>
end type command_t

```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

```

<Commands: command: TBP>≡
    procedure :: final => command_final

<Commands: procedures>≡
    recursive subroutine command_final (cmd)
        class(command_t), intent(inout) :: cmd
        if (associated (cmd%options)) then
            call cmd%options%final ()
            deallocate (cmd%options)
            call cmd%local%local_final ()
            deallocate (cmd%local)
        else
            cmd%local => null ()
        end if
    end subroutine command_final

```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

```

<Commands: procedures>+≡
    subroutine dispatch_command (command, pn)
        class(command_t), intent(inout), pointer :: command
        type(parse_node_t), intent(in), target :: pn

case default
    print *, char (parse_node_get_rule_key (pn))
    call msg_bug ("Command not implemented")
end select
command%pn => pn
end subroutine dispatch_command

```

Output. We allow for indentation so we can display a command tree.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_write), deferred :: write

⟨Commands: interfaces⟩≡
    abstract interface
        subroutine command_write (cmd, unit, indent)
            import
            class(command_t), intent(in) :: cmd
            integer, intent(in), optional :: unit, indent
        end subroutine command_write
    end interface

```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

```

⟨Commands: command: TBP⟩+≡
    procedure (command_compile), deferred :: compile

⟨Commands: interfaces⟩+≡
    abstract interface
        subroutine command_compile (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_compile
    end interface

```

Execute a command. This will use and/or modify the runtime data set. If the `quit` flag is set, the caller should terminate command execution.

```

<Commands: command: TBP>+≡
    procedure (command_execute), deferred :: execute

<Commands: interfaces>+≡
    abstract interface
        subroutine command_execute (cmd, global)
            import
            class(command_t), intent(inout) :: cmd
            type(rt_data_t), intent(inout), target :: global
        end subroutine command_execute
    end interface

```

37.1.2 Options

The `options` command list is allocated, initialized, and executed, if the command is associated with an option text in curly braces. If present, a separate local runtime data set `local` will be allocated and initialized; otherwise, `local` becomes a pointer to the global dataset.

For output, we indent the options list.

```

<Commands: command: TBP>+≡
    procedure :: write_options => command_write_options

<Commands: procedures>+≡
    recursive subroutine command_write_options (cmd, unit, indent)
        class(command_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: ind
        ind = 1; if (present (indent)) ind = indent + 1
        if (associated (cmd%options)) call cmd%options%write (unit, ind)
    end subroutine command_write_options

```

Compile the options list, if any. This implies initialization of the local environment. Should be done once the `pn_opt` node has been assigned (if applicable), but before the actual command compilation.

```

<Commands: command: TBP>+≡
    procedure :: compile_options => command_compile_options

<Commands: procedures>+≡
    recursive subroutine command_compile_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%pn_opt)) then
            allocate (cmd%local)
            call cmd%local%local_init (global)
            call global%copy_globals (cmd%local)
            allocate (cmd%options)
            call cmd%options%compile (cmd%pn_opt, cmd%local)
            call global%restore_globals (cmd%local)
            call cmd%local%deactivate ()
        end if
    end subroutine command_compile_options

```

```

    else
        cmd%local => global
    end if
end subroutine command_compile_options

```

Execute options. First prepare the local environment, then execute the command list.

```

<Commands: command: TBP>+≡
    procedure :: execute_options => cmd_execute_options

<Commands: procedures>+≡
    recursive subroutine cmd_execute_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call cmd%local%activate ()
            call cmd%options%execute (cmd%local)
        end if
    end subroutine cmd_execute_options

```

This must be called after the parent command has been executed, to undo temporary modifications to the environment. Note that some modifications to `global` can become permanent.

```

<Commands: command: TBP>+≡
    procedure :: reset_options => cmd_reset_options

<Commands: procedures>+≡
    subroutine cmd_reset_options (cmd, global)
        class(command_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        if (associated (cmd%options)) then
            call cmd%local%deactivate (global)
        end if
    end subroutine cmd_reset_options

```

37.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

```

<Commands: types>+≡
    type, extends (command_t) :: cmd_model_t
        private
        type(string_t) :: name
        contains
        <Commands: cmd model: TBP>
    end type cmd_model_t

```

Output

```

<Commands: cmd model: TBP>≡
    procedure :: write => cmd_model_write

```

```

<Commands: procedures>+≡
subroutine cmd_model_write (cmd, unit, indent)
  class(cmd_model_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,1x,'"',A,'\"') "model =", char (cmd%name)
end subroutine cmd_model_write

```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed.

Assign the model pointer in the `global` record, so it can be used for (read-only) variable lookup while compiling further commands.

```

<Commands: cmd model: TBP>+≡
  procedure :: compile => cmd_model_compile

<Commands: procedures>+≡
subroutine cmd_model_compile (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_name
  type(model_t), pointer :: model
  pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
  cmd%name = parse_node_get_string (pn_name)
  model => null ()
  if (associated (global%model)) then
    if (global%model%get_name () == cmd%name) model => global%model
  end if
  if (.not. associated (model)) then
    if (global%model_list%model_exists (cmd%name)) then
      model => global%model_list%get_model_ptr (cmd%name)
    else
      call global%read_model (cmd%name, model)
    end if
  end if
  global%model => model
  if (associated (global%model)) then
    call global%model%link_var_list (global%var_list)
  end if
end subroutine cmd_model_compile

```

Execute: Insert a pointer into the global data record and reassign the variable list.

```

<Commands: cmd model: TBP>+≡
  procedure :: execute => cmd_model_execute

<Commands: procedures>+≡
subroutine cmd_model_execute (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  call global%select_model (cmd%name)
  if (.not. associated (global%model)) &

```

```

        call msg_fatal ("Switching to model '" &
            // char (cmd%name) // "': model not found")
    end subroutine cmd_model_execute

```

Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_library_t
    private
    type(string_t) :: name
    contains
    ⟨Commands: cmd library: TBP⟩
end type cmd_library_t

```

Output.

```

⟨Commands: cmd library: TBP⟩≡
    procedure :: write => cmd_library_write

⟨Commands: procedures⟩+≡
    subroutine cmd_library_write (cmd, unit, indent)
        class(cmd_library_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit)
        call write_indent (u, indent)
        write (u, "(1x,A,1x,'"',A,'\"')") "library =", char (cmd%name)
    end subroutine cmd_library_write

```

Compile. Get the library name.

```

⟨Commands: cmd library: TBP⟩+≡
    procedure :: compile => cmd_library_compile

⟨Commands: procedures⟩+≡
    subroutine cmd_library_compile (cmd, global)
        class(cmd_library_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_name
        pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
        cmd%name = parse_node_get_string (pn_name)
    end subroutine cmd_library_compile

```

Execute: Initialize a new library and push it on the library stack (if it does not yet exist). Insert a pointer to the library into the global data record. Then, try to load the library unless the `rebuild` flag is set.

```

⟨Commands: cmd library: TBP⟩+≡
    procedure :: execute => cmd_library_execute

```

```

<Commands: procedures>+≡
subroutine cmd_library_execute (cmd, global)
  class(cmd_library_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(prclib_entry_t), pointer :: lib_entry
  type(process_library_t), pointer :: lib
  logical :: rebuild_library
  lib => global%prclib_stack%get_library_ptr (cmd%name)
  rebuild_library = &
    var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
  if (.not. (associated (lib))) then
    allocate (lib_entry)
    call lib_entry%init (cmd%name)
    lib => lib_entry%process_library_t
    call global%add_prclib (lib_entry)
  else
    call global%update_prclib (lib)
  end if
  if (associated (lib) .and. .not. rebuild_library) then
    call lib%update_status (global%os_data)
  end if
end subroutine cmd_library_execute

```

Process configuration

We define a process-configuration command as a specific type. The incoming and outgoing particles are given evaluation-trees which we transform to PDG-code arrays. For transferring to O'MEGA, they are reconverted to strings.

For the incoming particles, we store parse nodes individually. We do not yet resolve the outgoing state, so we store just a single parse node.

This also includes the choice of method for the corresponding process: `omega` for O'MEGA matrix elements as Fortran code, `ovm` for O'MEGA matrix elements as a bytecode virtual machine, `test` for special processes, `unit_test` for internal test matrix elements generated by WHIZARD, `template` and `template_unity` for test matrix elements generated by WHIZARD as Fortran code similar to the O'MEGA code. If the one-loop program (OLP) GoSam is linked, also matrix elements from there (at leading and next-to-leading order) can be generated via `gosam`.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_process_t
  private
  type(string_t) :: id
  integer :: n_in = 0
  type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
  type(parse_node_t), pointer :: pn_out => null ()
contains
  <Commands: cmd process: TBP>
end type cmd_process_t

```

Output. The particle expressions are not resolved, so we just list the number of incoming particles.

```

<Commands: cmd process: TBP>≡

```

```

    procedure :: write => cmd_process_write
  (Commands: procedures)+≡
    subroutine cmd_process_write (cmd, unit, indent)
      class(cmd_process_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = given_output_unit (unit); if (u < 0) return
      call write_indent (u, indent)
      write (u, "(1x,A,A,A,I0,A)") "process: ", char (cmd%id), " (", &
        size (cmd%pn_pdg_in), " -> X)"
      call cmd%write_options (u, indent)
    end subroutine cmd_process_write

```

Compile. Find and assign the parse nodes.

```

  (Commands: cmd process: TBP)+≡
    procedure :: compile => cmd_process_compile
  (Commands: procedures)+≡
    subroutine cmd_process_compile (cmd, global)
      class(cmd_process_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_id, pn_in, pn_codes
      integer :: i
      pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
      pn_in => parse_node_get_next_ptr (pn_id, 2)
      cmd%pn_out => parse_node_get_next_ptr (pn_in, 2)
      cmd%pn_opt => parse_node_get_next_ptr (cmd%pn_out)
      call cmd%compile_options (global)
      cmd%id = parse_node_get_string (pn_id)
      cmd%n_in = parse_node_get_n_sub (pn_in)
      pn_codes => parse_node_get_sub_ptr (pn_in)
      allocate (cmd%pn_pdg_in (cmd%n_in))
      do i = 1, cmd%n_in
        cmd%pn_pdg_in(i)%ptr => pn_codes
        pn_codes => parse_node_get_next_ptr (pn_codes)
      end do
    end subroutine cmd_process_compile

```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

```

  (Commands: cmd process: TBP)+≡
    procedure :: execute => cmd_process_execute

```

{Commands: procedures}+≡

```

subroutine cmd_process_execute (cmd, global)
  class(cmd_process_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(pdg_array_t) :: pdg_in, pdg_out
  type(pdg_array_t), dimension(:), allocatable :: pdg_out_tab

Command execution. Generate code, write driver, compile and link. Do this for all libraries in the list.

If no library names have been given and stored while compiling this command, we collect all libraries from the current stack and compile those.

We can compile static libraries (which actually just loads them). However, we can't incorporate in a generated executable.

<Commands: cmd compile: TBP>+≡

```

```

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

```

Clear values

This command clears the current values of variables or other objects, where this makes sense. It parallels the `show` command. The objects are cleared, but not deleted.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_clear_t
        private
        type(string_t), dimension(:), allocatable :: name
    contains
        ⟨Commands: cmd clear: TBP⟩
    end type cmd_clear_t

```

Output: list the names of the objects to be cleared.

```

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

If the expectation fails, an error condition is recorded.

```

⟨Commands: types⟩+=
    type, extends (command_t) :: cmd_expect_t
        private
            type(parse_node_t), pointer :: pn_lexpr => null ()
        contains
            ⟨Commands: cmd expect: TBP⟩
        end type cmd_expect_t

```

Simply tell the status.

```

⟨Commands: cmd expect: TBP⟩=
    procedure :: write => cmd_expect_write

⟨Commands: procedures⟩+=
    subroutine cmd_expect_write (cmd, unit, indent)
        class(cmd_expect_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        if (associated (cmd%pn_lexpr)) then
            write (u, "(1x,A)" "expect: [expression associated]"
        else
            write (u, "(1x,A)" "expect: [undefined]"
        end if
    end subroutine cmd_expect_write

```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

```

⟨Commands: cmd expect: TBP⟩+=
    procedure :: compile => cmd_expect_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_expect_compile (cmd, global)
  class(cmd_expect_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_arg
  pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_arg)
  cmd%pn_lexpr => parse_node_get_sub_ptr (pn_arg)
  call cmd%compile_options (global)
end subroutine cmd_expect_compile

```

Execute. Evaluate both arguments, print them and their difference (if numerical), and whether they agree. Record the result.

```

Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

```

<Commands: types>+≡
    type :: sentry_expr_t
        type(parse_node_p), dimension(:), allocatable :: expr
        contains
        <Commands: sentry expr: TBP>
    end type sentry_expr_t

```

Compile parse nodes into evaluation trees.

```

<Commands: sentry expr: TBP>≡
    procedure :: compile => sentry_expr_compile

<Commands: procedures>+≡
    subroutine sentry_expr_compile (sentry, pn)
        class(sentry_expr_t), intent(out) :: sentry
        type(parse_node_t), intent(in), target :: pn
        type(parse_node_t), pointer :: pn_expr, pn_extra
        integer :: n_expr, i
        n_expr = parse_node_get_n_sub (pn)

  end subroutine cmd_ren_scale_execute

```

Weight

Define a weight expression. The weight is applied to a process to be integrated, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_weight_t
    private
      type(parse_node_t), pointer :: pn_expr => null ()
    contains
      <Commands: cmd weight: TBP>
    end type cmd_weight_t
```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```
<Commands: cmd weight: TBP>≡
  procedure :: write => cmd_weight_write

<Commands: procedures>+≡
  subroutine cmd_weight_write (cmd, unit, indent)
    class(cmd_weight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "weight expression: [defined]"
  end subroutine cmd_weight_write
```

Compile. Simply store the parse (sub)tree.

```
<Commands: cmd weight: TBP>+≡
  procedure :: compile => cmd_weight_compile

<Commands: procedures>+≡
  subroutine cmd_weight_compile (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_weight_compile
```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```
<Commands: cmd weight: TBP>+≡
  procedure :: execute => cmd_weight_execute

<Commands: procedures>+≡
  subroutine cmd_weight_execute (cmd, global)
    class(cmd_weight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%weight_expr => cmd%pn_expr
  end subroutine cmd_weight_execute
```

Selection

Define a selection expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```
<Commands: types>+≡  
  type, extends (command_t) :: cmd_selection_t  
    private  
      type(parse_node_t), pointer :: pn_expr => null ()  
    contains  
      <Commands: cmd selection: TBP>  
    end type cmd_selection_t
```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```
<Commands: cmd selection: TBP>≡  
  procedure :: write => cmd_selection_write  
  
<Commands: procedures>+≡  
  subroutine cmd_selection_write (cmd, unit, indent)  
    class(cmd_selection_t), intent(in) :: cmd  
    integer, intent(in), optional :: unit, indent  
    integer :: u  
    u = given_output_unit (unit); if (u < 0) return  
    call write_indent (u, indent)  
    write (u, "(1x,A)") "selection expression: [defined]"  
  end subroutine cmd_selection_write
```

Compile. Simply store the parse (sub)tree.

```
<Commands: cmd selection: TBP>+≡  
  procedure :: compile => cmd_selection_compile  
  
<Commands: procedures>+≡  
  subroutine cmd_selection_compile (cmd, global)  
    class(cmd_selection_t), intent(inout) :: cmd  
    type(rt_data_t), intent(inout), target :: global  
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)  
  end subroutine cmd_selection_compile
```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```
<Commands: cmd selection: TBP>+≡  
  procedure :: execute => cmd_selection_execute  
  
<Commands: procedures>+≡  
  subroutine cmd_selection_execute (cmd, global)  
    class(cmd_selection_t), intent(inout) :: cmd  
    type(rt_data_t), intent(inout), target :: global  
    global%pn%selection_lexpr => cmd%pn_expr  
  end subroutine cmd_selection_execute
```

Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

```
<Commands: types>+≡
  type, extends (command_t) :: cmd_reweight_t
  private
    type(parse_node_t), pointer :: pn_expr => null ()
  contains
    <Commands: cmd reweight: TBP>
  end type cmd_reweight_t
```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

```
<Commands: cmd reweight: TBP>≡
  procedure :: write => cmd_reweight_write

<Commands: procedures>+≡
  subroutine cmd_reweight_write (cmd, unit, indent)
    class(cmd_reweight_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "reweight expression: [defined]"
  end subroutine cmd_reweight_write
```

Compile. Simply store the parse (sub)tree.

```
<Commands: cmd reweight: TBP>+≡
  procedure :: compile => cmd_reweight_compile

<Commands: procedures>+≡
  subroutine cmd_reweight_compile (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_reweight_compile
```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```
<Commands: cmd reweight: TBP>+≡
  procedure :: execute => cmd_reweight_execute

<Commands: procedures>+≡
  subroutine cmd_reweight_execute (cmd, global)
    class(cmd_reweight_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%reweight_expr => cmd%pn_expr
  end subroutine cmd_reweight_execute
```

Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

```
<Commands: types>+≡
    type, extends (command_t) :: cmd_alt_setup_t
        private
            type(parse_node_p), dimension(:), allocatable :: setup
        contains
            <Commands: cmd alt setup: TBP>
        end type cmd_alt_setup_t
```

Output. Print just a message that the alternative setup list has been defined.

```
<Commands: cmd alt setup: TBP>≡
    procedure :: write => cmd_alt_setup_write

<Commands: procedures>+≡
    subroutine cmd_alt_setup_write (cmd, unit, indent)
        class(cmd_alt_setup_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A,I0,A)") "alt_setup: ", size (cmd%setup), " entries"
    end subroutine cmd_alt_setup_write
```

Compile. Store the parse sub-trees in an array.

```
<Commands: cmd alt setup: TBP>+≡
    procedure :: compile => cmd_alt_setup_compile

<Commands: procedures>+≡
    subroutine cmd_alt_setup_compile (cmd, global)
        class(cmd_alt_setup_t), intent(inout) :: cmd
        type(rt_data_t), intent(inout), target :: global
        type(parse_node_t), pointer :: pn_list, pn_setup
        integer :: i
        pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
        if (associated (pn_list)) then
            allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
            i = 1
            pn_setup => parse_node_get_sub_ptr (pn_list)
            do while (associated (pn_setup))
                cmd%setup(i)%ptr => pn_setup
                i = i + 1
                pn_setup => parse_node_get_next_ptr (pn_setup)
            end do
        else
            allocate (cmd%setup (0))
        end if
    end subroutine cmd_alt_setup_compile
```

Execute. Transfer the array of command lists to the global environment.

```

<Commands: cmd alt setup: TBP>+≡
  procedure :: execute => cmd_alt_setup_execute

<Commands: procedures>+≡
  subroutine cmd_alt_setup_execute (cmd, global)
    class(cmd_alt_setup_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    if (allocated (global%pn%alt_setup)) deallocate (global%pn%alt_setup)
    allocate (global%pn%alt_setup (size (cmd%setup)), source = cmd%setup)
  end subroutine cmd_alt_setup_execute

```

Integration

Integrate several processes, consecutively with identical parameters.

```

<Commands: types>+≡
  type, extends (command_t) :: cmd_integrate_t
  private
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id
  contains
  <Commands: cmd integrate: TBP>
  end type cmd_integrate_t

```

Output: we know the process IDs.

```

<Commands: cmd integrate: TBP>≡
  procedure :: write => cmd_integrate_write

<Commands: procedures>+≡
  subroutine cmd_integrate_write (cmd, unit, indent)
    class(cmd_integrate_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u, i
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)", advance="no") "integrate ("
    do i = 1, cmd%n_proc
      if (i > 1) write (u, "(A,1x)", advance="no") ", "
      write (u, "(A)", advance="no") char (cmd%process_id(i))
    end do
    write (u, "(A)") ")"
  end subroutine cmd_integrate_write

```

Compile.

```

<Commands: cmd integrate: TBP>+≡
  procedure :: compile => cmd_integrate_compile

<Commands: procedures>+≡
  subroutine cmd_integrate_compile (cmd, global)
    class(cmd_integrate_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_proclist, pn_proc

```

```

integer :: i
pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
call cmd%compile_options (global)
cmd%n_proc = parse_node_get_n_sub (pn_proclist)
allocate (cmd%process_id (cmd%n_proc))
pn_proc => parse_node_get_sub_ptr (pn_proclist)
do i = 1, cmd%n_proc
  cmd%process_id(i) = parse_node_get_string (pn_proc)
  call global%process_stack%init_result_vars (cmd%process_id(i))
  pn_proc => parse_node_get_next_ptr (pn_proc)
end do
end subroutine cmd_integrate_compile

```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

The `integrate` procedure should take its input from the currently active local environment, but produce a process record in the stack of the global environment.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

```

⟨Commands: cmd integrate: TBP⟩+≡
  procedure :: execute => cmd_integrate_execute

⟨Commands: procedures⟩+≡

```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For the elements, we reuse the `cmd_plot_t` defined above.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_graph_t
  private
  type(string_t) :: id
  integer :: n_elements = 0
  type(cmd_plot_t), dimension(:), allocatable :: el
  type(string_t), dimension(:), allocatable :: element_id
  contains
  ⟨Commands: cmd graph: TBP⟩
end type cmd_graph_t

```

Output. Just print the ID.

```

⟨Commands: cmd graph: TBP⟩≡
  procedure :: write => cmd_graph_write

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_write (cmd, unit, indent)
    class(cmd_graph_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A,A,A,I0,A)") "graph: ", char (cmd%id), &
      " (", cmd%n_elements, " entries)"
  end subroutine cmd_graph_write

```

Compile. Record the graph ID and initialize lower, upper bound and bin width. For compiling the graph element syntax, we use part of the `cmd_plot_t` compiler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

```

⟨Commands: cmd graph: TBP⟩+≡
  procedure :: compile => cmd_graph_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_graph_compile (cmd, global)
    class(cmd_graph_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
    integer :: i

    pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
    pn_tag => parse_node_get_sub_ptr (pn_term)

```

```

cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
call cmd%compile_options (global)
select case (char (parse_node_get_rule_key (pn_tag)))
case ("analysis_id")
    cmd%id = parse_node_get_string (pn_tag)
case default
    call msg_bug ("graph: name expression not implemented (yet)")
end select

    cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
    call cmd%el(i)%init (pn_tag, global)
    cmd%element_id(i) = parse_node_get_string (pn_tag)
    pn_app => parse_node_get_next_ptr (pn_app)
end do

end subroutine cmd_graph_compile

```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

  call set_drawing_options (drawing_options, var_list)
  if (associated (cmd%el(i)%options)) then
    call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
  end if
  call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
end do
end subroutine cmd_graph_execute

```

Analysis

Hold the analysis ID either as a string or as an expression:

```

⟨Commands: types⟩+≡
  type :: analysis_id_t
  type(string_t) :: tag
  type(parse_node_t), pointer :: pn_sexpr => null ()
end type analysis_id_t

```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_analysis_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
  contains
  ⟨Commands: cmd analysis: TBP⟩
end type cmd_analysis_t

```

Output. Print just a message that analysis has been defined.

```

⟨Commands: cmd analysis: TBP⟩≡
  procedure :: write => cmd_analysis_write

⟨Commands: procedures⟩+≡
  subroutine cmd_analysis_write (cmd, unit, indent)
    class(cmd_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "analysis: [defined]"
  end subroutine cmd_analysis_write

```

Compile. Simply store the parse (sub)tree.

```

⟨Commands: cmd analysis: TBP⟩+≡
  procedure :: compile => cmd_analysis_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_analysis_compile (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
  end subroutine cmd_analysis_compile

```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

```

⟨Commands: cmd analysis: TBP⟩+≡
  procedure :: execute => cmd_analysis_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_analysis_execute (cmd, global)
    class(cmd_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    global%pn%analysis_lexpr => cmd%pn_lexpr
  end subroutine cmd_analysis_execute

```

Write histograms and plots

The data type encapsulating the command:

```

⟨Commands: types⟩+≡
  type, extends (command_t) :: cmd_write_analysis_t
  private
    type(analysis_id_t), dimension(:), allocatable :: id
    type(string_t), dimension(:), allocatable :: tag
  contains
    ⟨Commands: cmd write analysis: TBP⟩
  end type cmd_write_analysis_t

```

Output. Just the keyword.

```

⟨Commands: cmd write analysis: TBP⟩≡
  procedure :: write => cmd_write_analysis_write

⟨Commands: procedures⟩+≡
  subroutine cmd_write_analysis_write (cmd, unit, indent)
    class(cmd_write_analysis_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
    write (u, "(1x,A)") "write_analysis"
  end subroutine cmd_write_analysis_write

```

Compile.

```

⟨Commands: cmd write analysis: TBP⟩+≡
  procedure :: compile => cmd_write_analysis_compile

⟨Commands: procedures⟩+≡
  subroutine cmd_write_analysis_compile (cmd, global)
    class(cmd_write_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
    integer :: n, i
    pn_clause => parse_node_get_sub_ptr (cmd%pn)
    pn_args => parse_node_get_sub_ptr (pn_clause, 2)
    cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
    call cmd%compile_options (global)
    if (associated (pn_args)) then
      n = parse_node_get_n_sub (pn_args)
      allocate (cmd%id (n))
      do i = 1, n
        pn_id => parse_node_get_sub_ptr (pn_args, i)
        if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
          cmd%id(i)%tag = parse_node_get_string (pn_id)
        else
          cmd%id(i)%pn_sexpr => pn_id
        end if
      end do
    else
      allocate (cmd%id (0))
    end if
  end subroutine cmd_write_analysis_compile

```

The output format for real data values:

```

⟨Commands: parameters⟩+≡
  character(*), parameter, public :: &
    DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
  character(len=1), dimension(2), parameter, public :: &
    FORBIDDEN_ENDINGS1 = [ "o", "a" ]
  character(len=2), dimension(5), parameter, public :: &
    FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "lo", "la" ]
  character(len=3), dimension(14), parameter, public :: &
    FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
      "f95", "log", "ltp", "mpx", "pdf", "phs", "sin", "tex" ]

```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

```

⟨Commands: cmd write analysis: TBP⟩+≡
  procedure :: execute => cmd_write_analysis_execute

⟨Commands: procedures⟩+≡
  subroutine cmd_write_analysis_execute (cmd, global)
    class(cmd_write_analysis_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    var_list => cmd%local%get_var_list_ptr ()
    call write_analysis_wrap (var_list, global%out_files, &

```

```

        cmd%id, tag = cmd%tag)
    end subroutine cmd_write_analysis_execute

```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

(Commands: procedures)+≡

```

subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)

<Commands: procedures>+≡
  subroutine cmd_printf_execute (cmd, global)
    class(cmd_printf_t), intent(inout) :: cmd
    type(rt_data_t), intent(inout), target :: global
    type(var_list_t), pointer :: var_list
    type(string_t) :: string, file
```

```

type(eval_tree_t) :: sprintf_expr
logical :: advance
var_list => cmd%local%get_var_list_ptr ()
advance = var_list_get_lval (var_list, &
    var_str ("?out_advance"))
file = var_list_get_sval (var_list, &
    var_str ("out_file"))
call eval_tree_init_sexpr (sprintf_expr, cmd%sexpr, var_list)
call eval_tree_evaluate (sprintf_expr)
if (eval_tree_result_is_known (sprintf_expr)) then
    string = eval_tree_get_string (sprintf_expr)
    if (len (file) == 0) then
        call msg_result (char (string))
    else
        call file_list_write (global%out_files, file, string, advance)
    end if
end if
end subroutine cmd_printf_execute

```

Record data

The expression syntax already contains a **record** keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_record_t
    private
    type(parse_node_t), pointer :: pn_lexpr => null ()
    contains
    ⟨Commands: cmd record: TBP⟩
end type cmd_record_t

```

Output. With the compile hack below, there is nothing of interest to print here.

```

⟨Commands: cmd record: TBP⟩≡
    procedure :: write => cmd_record_write

⟨Commands: procedures⟩+≡
    subroutine cmd_record_write (cmd, unit, indent)
        class(cmd_record_t), intent(in) :: cmd
        integer, intent(in), optional :: unit, indent
        integer :: u
        u = given_output_unit (unit); if (u < 0) return
        call write_indent (u, indent)
        write (u, "(1x,A)") "record"
    end subroutine cmd_record_write

```

Compile. This is a hack which transforms the **record** command into a **record** expression, which we handle in the expressions module.

```

⟨Commands: cmd record: TBP⟩+≡
    procedure :: compile => cmd_record_compile

```

```

⟨Commands: procedures⟩+≡
subroutine cmd_record_compile (cmd, global)
  class(cmd_record_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
  call parse_node_create_branch (pn_lexpr, &
    syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `ds_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

```

Execute command: Simulate events. This is done via a `simulation_t` object and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a pending signal. The current logic ensures that the `es_array` output channels are closed before the `execute` routine returns. The program will terminate then in `command_list_execute`.

```

Range expressions

We need a special type for storing and evaluating range expressions.

```
(Commands: parameters)+≡  
  integer, parameter :: STEP_NONE = 0  
  integer, parameter :: STEP_ADD = 1  
  integer, parameter :: STEP_SUB = 2  
  integer, parameter :: STEP_MUL = 3  
  integer, parameter :: STEP_DIV = 4  
  integer, parameter :: STEP_COMP_ADD = 11  
  integer, parameter :: STEP_COMP_MUL = 13
```

There is an abstract base type and two implementations: scan over integers and scan over reals.

```
(Commands: types)+≡  
  type, abstract :: range_t  
    type(parse_node_t), pointer :: pn_expr => null ()  
    type(parse_node_t), pointer :: pn_term => null ()  
    type(parse_node_t), pointer :: pn_factor => null ()  
    type(parse_node_t), pointer :: pn_value => null ()  
    type(parse_node_t), pointer :: pn_literal => null ()  
    type(parse_node_t), pointer :: pn_beg => null ()  
    type(parse_node_t), pointer :: pn_end => null ()  
    type(parse_node_t), pointer :: pn_step => null ()  
    type(eval_tree_t) :: expr_beg  
    type(eval_tree_t) :: expr_end  
    type(eval_tree_t) :: expr_step  
    integer :: step_mode = 0  
    integer :: n_step = 0  
  contains  
    (Commands: range: TBP)  
  end type range_t
```

These are the implementations:

```
(Commands: types)+≡  
  type, extends (range_t) :: range_int_t  
    integer :: i_beg = 0  
    integer :: i_end = 0  
    integer :: i_step = 0  
  contains  
    (Commands: range int: TBP)  
  end type range_int_t  
  
  type, extends (range_t) :: range_real_t  
    real(default) :: r_beg = 0  
    real(default) :: r_end = 0  
    real(default) :: r_step = 0  
    real(default) :: lr_beg = 0  
    real(default) :: lr_end = 0  
    real(default) :: lr_step = 0  
  contains  
    (Commands: range real: TBP)  
  end type range_real_t
```

Finalize the allocated dummy node. The other nodes are just pointers.

```

<Commands: range: TBP>≡
    procedure :: final => range_final

<Commands: procedures>+≡
    subroutine range_final (object)
        class(range_t), intent(inout) :: object
        if (associated (object%pn_expr)) then
            call parse_node_final (object%pn_expr, recursive = .false.)
            call parse_node_final (object%pn_term, recursive = .false.)
            call parse_node_final (object%pn_factor, recursive = .false.)
            call parse_node_final (object%pn_value, recursive = .false.)
            call parse_node_final (object%pn_literal, recursive = .false.)
            deallocate (object%pn_expr)
            deallocate (object%pn_term)
            deallocate (object%pn_factor)
            deallocate (object%pn_value)
            deallocate (object%pn_literal)
        end if
    end subroutine range_final

```

Output.

end subroutine range_init

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

<Commands: range: TBP>+≡

Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the lhs). The rhs of this parse node is assigned from the available rhs expressions in the scan list, one at a time, so the compiled parse node can be prepended to the scan body.

Note: for the integer/real range array, the obvious implementation as a polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are apparently broken.

```

<Commands: types>+≡
type, extends (command_t) :: cmd_scan_t
private
type(string_t) :: name
integer :: n_values = 0
type(parse_node_p), dimension(:), allocatable :: scan_cmd
!!! !!! gfortran 4.7.x memory corruption
!!! class(range_t), dimension(:), allocatable :: range
type(range_int_t), dimension(:), allocatable :: range_int
type(range_real_t), dimension(:), allocatable :: range_real
contains
<Commands: cmd_scan: TBP>
end type cmd_scan_t

```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and

should not be finalized, so we should not call the finalizer recursively.

```

<Commands: cmd scan: TBP>≡
  procedure :: final => cmd_scan_final

<Commands: procedures>+≡
  recursive subroutine cmd_scan_final (cmd)
    class(cmd_scan_t), intent(inout) :: cmd
    type(parse_node_t), pointer :: pn_var_single, pn_decl_single

  end subroutine cmd_scan_final

```

Output.

```

<Commands: cmd scan: TBP>+≡
  procedure :: write => cmd_scan_write

<Commands: procedures>+≡
  subroutine cmd_scan_write (cmd, unit, indent)
    class(cmd_scan_t), intent(in) :: cmd
    integer, intent(in), optional :: unit, indent
    integer :: u
    u = given_output_unit (unit); if (u < 0) return
    call write_indent (u, indent)
  end subroutine cmd_scan_write

```

```

        write (u, "(1x,A,1x,A,1x,'(,I0,')')") "scan:", char (cmd%name), &
            cmd%n_values
    end subroutine cmd_scan_write

```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

```

```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

```

```

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of `else if` constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

```

⟨Commands: types⟩+≡
    type, extends (command_t) :: cmd_if_t

            call cmd%command_list%execute (global)
            call msg_message &
                ("End of included '" // char (cmd%file) // "'")
        end if
    end subroutine cmd_include_execute

```

Quit command execution

The code is the return code of the whole program if it is terminated by this command.

```

<Commands: types>+=
    type, extends (command_t) :: cmd_quit_t
        private
        logical :: has_code = .false.
        type(parse_node_t), pointer :: pn_code_expr => null ()
    contains
        <Commands: cmd quit: TBP>
    end type cmd_quit_t

```

Output.

```

<Commands: cmd quit: TBP>=
    procedure :: write => cmd_quit_write

```

```

<Commands: procedures>+≡
subroutine cmd_quit_write (cmd, unit, indent)
  class(cmd_quit_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  call write_indent (u, indent)
  write (u, "(1x,A,L1)") "quit: has_code = ", cmd%has_code
end subroutine cmd_quit_write

```

Compile: allocate a quit object which serves as a placeholder.

```

<Commands: cmd quit: TBP>+≡
  procedure :: compile => cmd_quit_compile

<Commands: procedures>+≡
subroutine cmd_quit_compile (cmd, global)
  class(cmd_quit_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_arg
  pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
  if (associated (pn_arg)) then
    cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
    cmd%has_code = .true.
  end if
end subroutine cmd_quit_compile

```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

```

<Commands: cmd quit: TBP>+≡
  procedure :: execute => cmd_quit_execute

<Commands: procedures>+≡
subroutine cmd_quit_execute (cmd, global)
  class(cmd_quit_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(var_list_t), pointer :: var_list
  logical :: is_known
  var_list => global%get_var_list_ptr ()
  if (cmd%has_code) then
    global%quit_code = eval_int (cmd%pn_code_expr, var_list, &
      is_known=is_known)
    if (.not. is_known) then
      call msg_error ("Undefined return code of quit/exit command")
    end if
  end if
  global%quit = .true.
end subroutine cmd_quit_execute

```

37.2.2 The command list

The command list holds a list of commands and relevant global data.

```
<Commands: public>+≡
    public :: command_list_t

<Commands: types>+≡
    type :: command_list_t
        ! not private anymore as required by the whizard-c-interface
        class(command_t), pointer :: first => null ()
        class(command_t), pointer :: last => null ()
    contains
        <Commands: command list: TBP>
    end type command_list_t
```

Output.

```
<Commands: command list: TBP>≡
    procedure :: write => command_list_write

<Commands: procedures>+≡
    recursive subroutine command_list_write (cmd_list, unit, indent)
        class(command_list_t), intent(in) :: cmd_list
        integer, intent(in), optional :: unit, indent
        class(command_t), pointer :: cmd
        cmd => cmd_list%first
        do while (associated (cmd))
            call cmd%write (unit, indent)
            cmd => cmd%next
        end do
    end subroutine command_list_write
```

Append a new command to the list and free the original pointer.

```
<Commands: command list: TBP>+≡
    procedure :: append => command_list_append

<Commands: procedures>+≡
    subroutine command_list_append (cmd_list, command)
        class(command_list_t), intent(inout) :: cmd_list
        class(command_t), intent(inout), pointer :: command
        if (associated (cmd_list%last)) then
            cmd_list%last%next => command
        else
            cmd_list%first => command
        end if
        cmd_list%last => command
        command => null ()
    end subroutine command_list_append
```

Finalize.

```
<Commands: command list: TBP>+≡
    procedure :: final => command_list_final
```

```

<Commands: procedures>+≡
recursive subroutine command_list_final (cmd_list)
  class(command_list_t), intent(inout) :: cmd_list
  class(command_t), pointer :: command
  do while (associated (cmd_list%first))
    command => cmd_list%first
    cmd_list%first => cmd_list%first%next
    call command%final ()
    deallocate (command)
  end do
  cmd_list%last => null ()
end subroutine command_list_final

```

37.2.3 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

```

<Commands: command list: TBP>+≡
  procedure :: compile => command_list_compile

<Commands: procedures>+≡
recursive subroutine command_list_compile (cmd_list, pn, global)
  class(command_list_t), intent(inout), target :: cmd_list
  type(parse_node_t), intent(in), target :: pn
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_cmd
  class(command_t), pointer :: command
  integer :: i
  pn_cmd => parse_node_get_sub_ptr (pn)
  do i = 1, parse_node_get_n_sub (pn)
    call dispatch_command (command, pn_cmd)
    call command%compile (global)
    call cmd_list%append (command)
    call terminate_now_if_signal ()
    pn_cmd => parse_node_get_next_ptr (pn_cmd)
  end do
end subroutine command_list_compile

```

37.2.4 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

```

<Commands: command list: TBP>+≡
  procedure :: execute => command_list_execute

<Commands: procedures>+≡
recursive subroutine command_list_execute (cmd_list, global)
  class(command_list_t), intent(in) :: cmd_list
  type(rt_data_t), intent(inout), target :: global

```

```

class(command_t), pointer :: command
command => cmd_list%first
COMMAND_COND: do while (associated (command))
    call command%execute_options (global)
    call command%execute (global)
    call command%reset_options (global)
    call terminate_now_if_signal ()
    if (global%quit) exit COMMAND_COND
    command => command%next
end do COMMAND_COND
end subroutine command_list_execute

```

37.2.5 Command list syntax

```

<Commands: public>+≡
    public :: syntax_cmd_list

<Commands: variables>≡
    type(syntax_t), target, save :: syntax_cmd_list

<Commands: public>+≡

⟨Standard module head⟩

```

    <WHIZARD: public>

    <WHIZARD: types>

    save

contains

    <WHIZARD: procedures>

end module whizard

```

37.3.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

```

<WHIZARD: public>≡
    public :: whizard_options_t
<WHIZARD: types>≡
    type :: whizard_options_t
        type(string_t) :: preload_model
        type(string_t) :: default_lib
        type(string_t) :: preload_libraries
        logical :: rebuild_library = .false.
        logical :: recompile_library = .false.
        logical :: rebuild_user
        logical :: rebuild_phs = .false.
        logical :: rebuild_grids = .false.
        logical :: rebuild_events = .false.
    end type whizard_options_t

```

37.3.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

```

<WHIZARD: types>+≡
    type, extends (parse_tree_t) :: pt_entry_t
        type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t

```

This is the stack. Since we always prepend, we just need the `last` pointer.

```

<WHIZARD: types>+≡
    type :: pt_stack_t
        type(pt_entry_t), pointer :: last => null ()
    contains
        <WHIZARD: pt stack: TBP>

```

```
end type pt_stack_t
```

The finalizer is called at the very end.

```
<WHIZARD: pt_stack: TBP>≡
  procedure :: final => pt_stack_final

<WHIZARD: procedures>≡
  subroutine pt_stack_final (pt_stack)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(pt_entry_t), pointer :: current
    do while (associated (pt_stack%last))
      current => pt_stack%last
      pt_stack%last => current%previous
      call parse_tree_final (current%parse_tree_t)
      deallocate (current)
    end do
  end subroutine pt_stack_final
```

Create and push a new entry, keeping the previous ones.

```
<WHIZARD: pt_stack: TBP>+≡
  procedure :: push => pt_stack_push

<WHIZARD: procedures>+≡
  subroutine pt_stack_push (pt_stack, parse_tree)
    class(pt_stack_t), intent(inout) :: pt_stack
    type(parse_tree_t), intent(out), pointer :: parse_tree
    type(pt_entry_t), pointer :: current
    allocate (current)
    parse_tree => current%parse_tree_t
    current%previous => pt_stack%last
    pt_stack%last => current
  end subroutine pt_stack_push
```

37.3.3 The whizard object

An object of type `whizard_t` is the top-level wrapper for a `WHIZARD` instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

```
<WHIZARD: public>+≡
  public :: whizard_t
```

```

<WHIZARD: types>+=
  type :: whizard_t
    type(whizard_options_t) :: options
    type(rt_data_t) :: global
    type(pt_stack_t) :: pt_stack
  contains
    <WHIZARD: whizard: TBP>
  end type whizard_t

```

37.3.4 Initialization and finalization

```

<WHIZARD: whizard: TBP>=
  procedure :: init => whizard_init

<WHIZARD: procedures>+=
  subroutine whizard_init (whizard, options, paths, logfile)
    class(whizard_t), intent(out), target :: whizard
    type(whizard_options_t), intent(in) :: options
    type(paths_t), intent(in), optional :: paths
    type(string_t), intent(in), optional :: logfile
    call init_syntax_tables ()
    whizard%options = options
    call whizard%global%global_init (paths, logfile)
    call whizard%init_rebuild_flags ()
    call whizard%preload_model ()
    call whizard%preload_library ()
    call whizard%global%init_fallback_model &
      (var_str ("SM_hadrons"), var_str ("SM_hadrons.mdl"))
  end subroutine whizard_init

```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

```

<WHIZARD: whizard: TBP>+=
  procedure :: final => whizard_final

<WHIZARD: procedures>+=
  subroutine whizard_final (whizard)
    class(whizard_t), intent(inout), target :: whizard
    call whizard%global%final ()

end subroutine whizard_preload_library

```

37.3.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

```

<WHIZARD: public>+≡
  public :: init_syntax_tables
  public :: final_syntax_tables

<WHIZARD: procedures>+≡
subroutine init_syntax_tables ()
  call syntax_model_file_init ()
  call syntax_phs_forest_init ()
  call syntax_pexpr_init ()

```

```

    call syntax_slha_init ()
    call syntax_blha_contract_init ()
    call syntax_cmd_list_init ()
end subroutine init_syntax_tables

subroutine final_syntax_tables ()
    call syntax_model_file_final ()
    call syntax_phs_forest_final ()
    call syntax_pexpr_final ()
    call syntax_slha_final ()
    call syntax_blha_contract_final ()
    call syntax_cmd_list_final ()
end subroutine final_syntax_tables

```

Write the syntax tables to external files.

```

<WHIZARD: public>+≡
    public :: write_syntax_tables

<WHIZARD: procedures>+≡
    subroutine write_syntax_tables ()

37.4 Driver program

The main program handles command options, initializes the environment, and runs WHIZARD in a particular mode (interactive, file, standard input).

This is also used in the C interface:

⟨Main: cmdline arg len declaration⟩≡
 integer, parameter :: CMDLINE_ARG_LEN = 1000

The actual main program:

⟨main.f90⟩≡
⟨File header⟩

```

program main

```

```

⟨Use strings⟩
    use unit_tests
    use system_dependencies
    use diagnostics
    use ifiles
    use os_interface
    use whizard

```

```

    implicit none

```

⟨Main: cmdline arg len declaration⟩

```

    ! Main program variable declarations
    character(CMDLINE_ARG_LEN) :: arg
    character(2) :: option
    type(string_t) :: long_option, value
    integer :: i, j, arg_len, arg_status
    logical :: look_for_options
    logical :: interactive
    logical :: banner
    type(string_t) :: files, this, model, default_lib, library, libraries
